SUMMARY

Synthesis of prostanoids in Crohn's disease was investigated using rectal biopsy specimens maintained in organ culture. As with ulcerative colitis increased synthesis of prostaglandin (PG)E2 was observed when the mucosa was inflamed, compared with uninfamed mucosa in Crohn's disease, and with control biopsy specimens. In contrast with ulcerative colitis differences from control specimens were observed even in the absence of inflammation. There was a raised synthesis of thromboxane (Tx)B2 (stable breakdown product of TxA2); concentrations of 6-keto PGF1α (stable breakdown product of prostacyclin) were unchanged and hence the ratio of 6-keto PGF1α/TxB2 was reduced. These changes might lead to an altered cytoprotective capacity or reduced suppressor cell activity, such as has previously been reported in intestinal lymphocytes in Crohn's disease.

In ulcerative colitis several studies have shown that increased synthesis of prostanoids such as PGE2, PGF2α, TxB2, and 6-keto PGF1α occurs during relapse. Fundamental differences from normal have not been shown in remission. The significance of these findings is unclear as thromboxane A2 and prostacyclin have powerful opposing actions and it has been suggested that an imbalance in the synthesis of these two prostanoids may be of pathological significance in several disease states.

Data on mucosal prostaglandin synthesis in Crohn's disease are lacking although peripheral blood mononuclear cells have been shown to synthesise increased amounts of PGE2 and TxB2 during relapse. In the present study we have investigated basal synthesis of PGE2, TxB2, and 6-keto PGF1α by rectal mucosa from patients with Crohn's disease maintained in organ culture. The study shows a deviation from normal in the synthesis of TxB2 and its relationship to 6-keto PGF1α even in the absence of inflammation.

Methods

PATIENTS

Seventeen patients with Crohn's disease (mean age 40-7±3-6 SEM years) were studied and compared with seven control patients (mean age 53-1±9-3 years). All the patients studied were British. The diagnosis of Crohn's disease was established on the basis of histology of biopsy or resected specimens and on radiological appearances. Details of the distribution of the Crohn's disease based upon evidence available at the time of biopsy are shown in the Table.

Inflammation was judged on sigmoidoscopic appearances supported by a routine histological examination. All biopsies that were considered inflamed came from reddened areas with loss of vascular pattern, granularity, and either spontaneous haemorrhage or haemorrhagic friability. The mucosa was considered uninfamed if it was pearly with a clearly visible vascular pattern and no sign of haemorrhage. Biopsies from equivocal

All the patients with large bowel Crohn's disease had rectal involvement, though some were uninfamed at the time of biopsy.
mucosa were not used. At the time of study the rectal mucosa was diffusely inflamed in seven cases; five patients had rectal disease sufficiently localised for biopsy specimens from both sigmoidoscopically inflamed and uninflamed mucosa to be taken. In six cases the rectal mucosa was uninflamed and in four of these the disease was apparently confined to the small bowel or ileocaecal region and there had never been evidence of rectal involvement.

The drugs used in the treatment of Crohn's disease at the time of biopsy were sulphasalazine (n=4), prednisolone (n=1), sulphasalazine and prednisolone (n=3), or sulphasalazine and azathioprine (n=2): seven patients were untreated at the time of biopsy. The control biopsy specimens were taken during the investigation of untreated patients with irritable colon syndrome (n=2), gastrointestinal blood loss (n=2), transient diarrhoea (n=1), small bowel lymphoma (n=1), and for the exclusion of amyloid (n=1). The specimens were histologically normal and in none was any organic disease involving the rectum shown.

Rectal biopsy specimens were excised 6 to 10 cm from the anus by forceps biopsy. The median biopsy weights were 8 mg (range 5–18 mg) for the patients with Crohn's disease and 13 mg (3–16 mg) for the control patients. After excision the biopsy specimens were washed in RPMI 1640 culture medium and cleaned of blood. They were placed in organ culture using RPMI 1640 containing penicillin (100 U/ml) and streptomycin (100 µg/ml) and cultured at 37°C in a vacuum jar containing 95% oxygen/5% CO₂. No fetal calf serum was added to the medium as albumin interferes with the assay of TxB₂. The culture medium was changed after one hour and the culture continued for a further 23 hours. The synthesis of PGE₂, TxB₂, and 6-keto PGF₁α, judged by their accumulation in the medium at the end of culture, was measured, as previously described, by specific radioimmunoassays, performed without knowledge of the source of the samples.

**Fig. 1** Synthesis of prostanoids in organ culture. Data from individual biopsy specimens are shown. For each prostanoid synthesis is expressed as ng/mg wet weight over 23 hours.
Imbalance of prostacyclin and thromboxane synthesis in Crohn's disease

Fig. 2 Ratio of 6-keto PGF₁α/TxB₂ synthesis. Data from individual biopsy specimens are shown. For each specimen the synthesis of 6-keto PGF₁α (in ng/mg wet weight/23 hours) has been expressed as a proportion of the synthesis of TxB₂ (in ng/mg net weight/23 hours).

STATISTICAL METHODS

As with prostaglandin synthesis in ulcerative colitis the distribution of the results was skewed and comparisons between groups were, therefore, made by the non-parametric Mann Whitney U test, using two tailed significance values. In the text median values are quoted and the range of individual values is shown in Figs 1 and 2. Paired comparisons between inflamed and uninflamed mucosa from patients with local rectal involvement were evaluated using the Sign test.

Results

(i) PGE₂: Inflamed mucosa from patients with Crohn's disease (n=12) synthesised significantly more PGE₂ than uninflamed mucosa (n=11) from patients with Crohn's disease (median values 4.67 ng/mg, 13.34 pmol/mg wet weight vs 2.22 ng/mg, 6.34 pmol/mg, p<0.02). The synthesis of PGE₂ by the seven control biopsies (median 1.25 ng/mg, 3.57 pmol/mg) did not differ significantly from that seen in uninflamed mucosa in Crohn's disease (p>0.10) but was significantly lower than the amount of PGE₂ synthesised by the inflamed mucosa (p=0.02). The range of individual values is shown in Fig. 1.

Where paired comparisons were made in patients with patchy involvement of the rectum all five showed greater synthesis of PGE₂ by sigmoidoscopically inflamed than by uninflamed mucosa.

(ii) TxB₂: The median amounts of TxB₂ synthesised in Crohn's disease were 0.70 ng/mg, 1.89 pmol/mg (inflamed mucosa n=11) and 0.90 ng/mg, 2.43 pmol/mg (uninflamed mucosa n=11). These values did not differ significantly from each other but with both inflamed and uninflamed mucosa the synthesis of TxB₂ was significantly higher than was observed in the control patients (median synthesis 0.18 ng/mg, 0.49 pmol/mg, n=7, p<0.05 compared with uninflamed, p<0.02 compared with inflamed mucosa from patients with Crohn's disease). High rates of TxB₂ synthesis were seen in two of the patients with Crohn's disease where the rectum was apparently unininvolved.

(iii) 6-Keto PGF₁α: No significant differences could be shown for the synthesis of 6-keto PGF₁α between inflamed (median 0.63 ng/mg, 1.70 pmol/mg) or uninflamed mucosa (median 0.33 ng/mg, 0.89 pmol/mg) from patients with Crohn's disease or uninflamed mucosa from the control patients (median 0.41 ng/mg, 1.11 pmol/mg). The ratio of 6-keto PGF₁α to TxB₂ synthesis, however, was significantly higher in the control biopsy specimens (median ratio 1.47) compared with both inflamed (median ratio 0.52; p<0.05) and uninflamed mucosa (median ratio 0.62, p<0.02) from patients with Crohn's disease. The difference between the control biopsy specimens and those with uninflamed mucosa with Crohn's disease remains significant (p=0.05) if the uninflamed biopsy specimens from patients with localised inflammation are excluded.

Six of the seven control patients showed a ratio greater than 1.0 whereas in only six out of 22 of the specimens from patients with Crohn's disease was it greater than 1.0. These results are shown in full in Fig. 2.

Discussion

As with previous studies concerning ulcerative colitis, the synthesis of PGE₂ by inflamed rectal mucosa has been shown to be enhanced in Crohn's disease. This may be a secondary consequence of invasion of the lamina propria by inflammatory mononuclear cells, but it may nevertheless contribute to the modulation of local inflammatory and immune responses. The finding of increased TxB₂ synthesis by rectal mucosa from patients with
Crohn’s disease, even in the absence of inflammation, was unexpected but might be of pathogenic significance. It could have arisen artefactually as a result of occult inflammation in apparently normal mucosa but against this proposition is the fact that an analogous effect was not shown for PGE₂. Furthermore, the raised synthesis of TxB₂ in two patients who had never had apparent rectal involvement raises the possibility – which requires confirmation – that this change may occur in the absence of clinically evident disease. As with ulcerative colitis²⁴ there is a wide scatter of results and overlap between individuals of different groups. The findings of a significant rise of thromboxane synthesis and a significant reduction in the 6-keto PGF₁α/TxB₂ ratio in Crohn’s disease even in the absence of inflammation thus apply to the groups rather than to all individuals.

These differences between the groups could have arisen in two ways. The most obvious explanation is that they arose because of a fundamental difference between the control patients and the patients with Crohn’s disease. Most of the patients with Crohn’s disease, however, were taking sulphasalazine, prednisolone, or azathioprine and an alternative explanation is that the results arose as a result of a pharmacological effect of treatment. If this were so our results could be in contradiction to data from previous work. This has shown that sulphasalazine, 5-amino salicylic acid, corticosteroids, and azathioprine can inhibit thromboxane and prostaglandin synthesis by rectal mucosa,²⁴ that under some circumstances 5-amino salicylic acid can enhance synthesis of prostacyclin and PGF₂α,⁵ and that sulphasalazine can inhibit degradation of PGE₂ and PGF₂α.⁹ On the basis of these data one would predict that treatment with sulphasalazine, corticosteroids, and azathioprine would lead to reduced rather than enhanced synthesis of TxB₂; if the increased synthesis of TxB₂ and reduced 6-keto PGF₁α/TxB₂ ratio we have observed in Crohn’s disease is due to the disease process, treatment with sulphasalazine could oppose these changes both by reducing thromboxane synthesis and by enhancing prostacyclin synthesis.⁴⁸

Increased thromboxane synthesis may occur as a result of platelet activation but the results are unlikely to be due to contamination by blood as the biopsies were meticulously cleaned of blood and rejected if contaminated. Cells other than platelets are more likely to be the source of thromboxane – for example, macrophages or other leucocytes.¹⁰ Synthesis of prostanoids by peripheral blood mononuclear cells has been shown to be elevated in Crohn’s disease.⁵ TxB₂ appears to be the predominant product of the cyclo-oxygenase pathway of human monocytes and neutrophils; these cells synthesise little if any prostacyclin¹⁰ and their accumulation in the mucosa may account for the rise of TxB₂ synthesis and the altered 6-keto PGF₁α/TxB₂ ratio that we have shown in Crohn’s disease. The inflammatory mediators leukotrienes C₄ and D₄ are potent stimuli for the synthesis of TxB₂ by rat peritoneal macrophages¹¹ and this raises the possibility that the increased thromboxane synthesis in Crohn’s disease may thus represent a sign of increased activation of the lipooxygenase pathways which are known to exist in human colonic mucosa.¹²

Regardless of the source of the TxB₂ its increased synthesis and altered relationship to prostacyclin synthesis could have several consequences which may be of pathological significance in Crohn’s disease. Increased platelet aggregability and local vasoconstriction are the best characterised consequences of thromboxane synthesis although there is little prior evidence to suggest that these processes are of primary importance in Crohn’s disease. Thromboxane and some lipoxygenase products may lead to reduced suppressor cell activity while other prostaglandins have an opposite effect.¹³ Our findings of increased TxB₂ synthesis in Crohn’s disease are, therefore, of particular interest in the light of a recent report of reduced suppressor cell activity in intestinal lymphocytes¹⁴ in Crohn’s disease. There is an intimate relationship between macrophage prostaglandin synthesis and lymphocyte function¹⁵ and local prostaglandin synthesis is known to have potent effects upon the functional characteristics of intra-mucosal lymphocytes.¹⁶ Enhanced thromboxane synthesis by macrophages in Crohn’s disease may thus play an important role in the downward modulation of intra-mucosal suppressor cell function.

Additionally prostaglandins have been proposed to have ‘cytoprotective’ properties in the colon¹⁷ as they do in the stomach. The evidence for prostaglandin ‘cytoprotection’ in the colon is at present rather limited but in the stomach there is abundant evidence that PGE₂ and prostacyclin protect against ulceration and cell damage;¹⁸ conversely, excessive thromboxane synthesis is associated with necrosis and ulceration.¹⁹ The finding of increased thromboxane synthesis and an alteration in the balance of 6-keto PGF₁α and TxB₂ synthesis raises the possibility of analogous consequences in the colon. Such a conclusion, however, must remain speculative as substantial doubt exists whether prostacyclin has any action affecting the colon which can reasonably be described as cytoprotection.

Prostaglandin synthesis in inflammatory bowel disease has previously been seen in terms of the
Imbalance of prostacyclin and thromboxane synthesis in Crohn's disease

generation of the mucosal inflammation and a global increase in the synthesis of prostanoids. We have used the ratio of prostacyclin to thromboxane synthesis to draw attention to the importance of the balance between synthesis of prostanoids with differing inflammatory, immunological, or perhaps 'cytoprotective' properties. The effect of treatment on this balance requires further clarification. Other imbalances might have been apparent if lipoxygenase products had been measured and the results emphasise the need to define further the spectrum of potential inflammatory mediators synthesised by the colonic mucosa in health and disease.
