The Role of the Hepatic Radionuclide Angiography in the Portal Perfusion Assessment in Cirrhosis and Liver Tumours

V Arito, K. Kostić, M. Perišić-Savić. Janošević Institute of Nuclear Medicine, Medical School and Clinical Center, Belgrade, YU

The aim of the study is the examination of the relative portal blood flow, by assessment of the hepatic perfusion index (HPI) in different degrees of hemo-
dynamic alterations related to liver cirrhosis and some focal liver diseases. Hepatic radionuclide angiography (HRA) was performed with bolus injection of 740 MBq 99m-Tc-pertechnetate, during one minute (1 tsec), using ROTA scintillation camera and Micro Delta computer (Siemens). HPI was estimated using Sarper's method of slope analysis.

In 10 controls, HPI was 0.68 ± 0.06; it was significantly decreased (p < 0.01) in 5 patients with chronic active hepatitis (HAH, 0.57 ± 0.03). 13 with liver cirrhosis without (LC, X = 0.49 ± 0.13) and 18 with esophageal varices (LCVE, X = 0.32 ± 0.19), as well as in 4 patients with LC and sclerosated esophageal varices (LCSEV, X = 0.16 ± 0.11). Comparing to HAH and LC (HAH-LC, p > 0.05), HPI values were significantly lower in LCVE (p < 0.01) and LCSEV (p < 0.05), while the values between the last two groups didn't differ (p > 0.05).

In 22 patients with liver hemangiomas (LH, X = 0.64 ± 0.08) HPI values were physiological (C-LH, p > 0.00). However, in 4 patients with hepatocellular carcinoma (HCC, HPI 0.20 ± 0.20), and 8 with liver metastases (LM, X = 0.40 ± 0.28), HPI values were significantly decreased (p < 0.01), but they didn't differ between themselves (H-LM, p = 0.05).

Portal liver perfusion decreases in respect to the portal hypertension and collateral circulation development. Thus, significant difference is proved be-
tween HPI values in cirrhotic patients with and without esophageal varices, while after sclerotherapy, HPI remains very low. Considering that in patients with hemangiomas, HPI values are normal, which is not the case in those with primary carcinomas and metastases, HRA is a useful method for the dif-
f erential diagnosis of hemangiomas and primary liver carcinomas, together with ultrasonography and blood pool scintigraphy.

Endoscopic Aspects in Portal Hypertensive Gastropathy

Ch. Banciu, Tr. Banciu, D. Iuculunu, S. Cotul, Leila Šušan, Elena Potenz. IVth Dept. of Internal Medicine, University of Medicine and Pharmacy Timisoara, Romania

The object of the study is an assessment of the endoscopic aspects of the gastric mucosa in patients with portal hypertension (PHT) and hepatic cirrhoses (HC), together with an estimation of the underlying histological changes leading to these modifications, and also a comparison with the ul-
trasongraphic, laparoscopic and splenoportographic modifications.

Material and Methods: The study was carried out on 60 patients with PHT and HC in different evolution stages. Eso-gastro-duodenoendoscopy was per-
formed in all patients, and the modifications of the gastric mucosa were de-
termined. In some patients antral and fundic biopsies were taken. The endo-
scopic aspects were correlated with the Child-Pugh stages of HC and com-
pared with the ultrasonographic, laparoscopic and splenoportographic signs of PHT.

Results: Four types of endoscopic gastric mucosa modifications were noted: (1) A scarlatina rash and superficial erythema in 10 cases (16.6%), with no significant histological changes. An inflammatory infiltration of the gastric mucosa was seen in six cases with alcoholic cirrhoses. (2) The mosaic pattern (snake skin), in 15 cases (25%), seen as a fine reticular pattern separating ar-
eas of erythematous edematous and normal mucosa, localized mostly in the antrum, but also in the fundic area of the stomach, and even on the duode-
um; histologically, there were no significant changes, but electron micro-
scopic findings revealed ecisfic submucosal capillaries. (3) Cherry red spots and diffuse hemorrhagic gastritis in 12 cases (20%). Five of these patients had upper gastrointestinal bleedings. Histology revealed submucosal venous and capillary dilatation and submucosal inflammatory changes in eight cases. (4) Gastric cardial varices (stages’ I–3) in 14 cases (23.3%), often associated with esophageal ones. Three of the patients were bleeding from these varices. None of the patients (15%) had normal gastric mucosa, without any modific-
ations.

The ultrasonography, laparoscopy and isotopic splenoportography (with 119 In, and the determination of the spleno-porto-cardiac circulation time) confirmed the presence of elements of PHT in all patients with erythema and varices at the gastric level. A good correlation with the evolutionary stages of HC has been noted.

Conclusions: The presence of a congestive gastropathy in patients with PHT and HC has been demonstrated. The gastric inflammatory infiltration was present in 28% of the cases, in correlation with the alcoholic etiology of HC.

Doppler Ultrasoundography (US) Examination of Portal Circulation After Transjugular Intrahepatic Portosystemic Shunt (TIPS)

A. De Santis, O. Riggio, M. Merli, R. Servi, T. Stati, F. Montagnese, P. Rossi, L. Capocaccia. 2° Gastroenterol., Radiologia, Univ. "La Sapienza" di Roma, Italy

TIPS is a radiological method for treating upper gastrointestinal bleeding in cirrhotic patients. TIPS has been shown to decrease the portosystemic gradient by about 40%. Little is known of the effects of TIPS on portal hemo-
dynamics. We examined 15 patients (9 M, 6 F, age range 53–72 yrs) who underwent TIPS for variceal bleeding (13 pts) or intractable ascites (2 pts). A doppler US was performed before and after 48 hrs, 7 days, 1, 3 and 6 months after TIPS. The following parameters were measured: maximum (VMax) and average (Vmean) velocity of blood flow (cm/sec) in the portal (PV), splenic (SV) superior mesenteric (SMV) veins and stent.

*p < 0.05 at least vs basal (paired T test)

The stent mean diameter was 6.9 ± 0.6 mm. After 3 months the VMax in the PV, SV and SMV increased by 104%, 86% and 90% respectively. In 4 patients (26%), after 48 hrs, a thrombosis of the left branch of the PV occurred which later disappeared. Conclusion: TIPS causes a major increase in blood flow velocity in portal vessels. The VMean maximum increase in the stent is reached at 3 months, while a decrease is observed at 6 months. After TIPS a transient thrombosis of the intrahepatic portal branch was observed in some cases.

Complications and Risks of Transjugular Intrahepatic Portosystemic Shunts in 28 Consecutive Patients

P. Hulek, A. Krajna, P. Elias, A. Michl, V. Safka, J. Erben, M. Volfová. Charles University Hospital, Hradec Kralove, Czech Republic

Purpose: Transjugular intrahepatic portosystemic shunt (TIPS) is used as a safe and effective method for the treatment of symptomatic portal hypo-
pertension. However, there are significant risks of hepatic encephalopathy and the shunt stenosis. These risks and technical complications were reviewed.

Material and Methods: Twenty eight consecutive mostly cirrhotic patients were treated with TIPS for variceal bleeding (78%) and intractable ascites (22%). There were no follow-ups ranging from 16 to 26 months (mean 18 months). Shunt pa-
tency was evaluated by doppler sonography. Shunt velocities below 25 cm/s indicated stenosis. Results: Technical success was achieved in 100%. 30-day mortality was 11%. Early (within 48 hours) thrombosis of the shunt occurred in 3 patients (11%). All these shunts were recanalised. Significant stenosis of the shunt was found in 3 patients and shunt occlusion occurred in 1 patient within 3 to 14 months after TIPS. The stenotic shunts responded well to angioplasty and parallel stent was performed in the patient with shunt oc-
clusion. Progression of hepatic encephalopathy occurred in 4 patients (15%). The thrombus formation in portal vein during the procedure was observed in 2 cases and was aspirated or lysed by local streptokinase infusion. The me-
diastinal hematoma caused by the brachiocephalic vein injury occurred in 1 patient. Conclusion: (1) Early shunt thrombosis or chronic shunt stenosis are amenable to recanalisation or balloon dilatation. (2) Doppler ultrasoundography is accurate in noninvasively assessing shunt stenosis following TIPS. 3) At this time, TIPS placement without careful follow-up should not be considered as a long term treatment for symptomatic portal hypertension.

Nutritional Status, Energy Expenditure and Portal Hypertension

J.B. Ksiażyk, J. Socha, M. Łyszkowska. Child Health Centre, Warsaw, Poland

Estimation of energy expenditure and nutritional assessment may define en-
ergy requirements that are of importance in chronic disorder when energy need is either from normal weight and in a number of liver diseases (DuBois equation) were used to construct the standard diagram of newly de-
developed age and sex-dependent anthropometric coefficient (AC) for the popu-
lation 4–18 years on the basis of the equation: AC = WH² / BS. AC enabled to express nutritional status in a single number that was within the normal range (AC ≥ s.p. standard deviation) or beyond, indicating nutritional prob-
lems. Statistical analysis was performed using unpaired t-test and Yates cor-
rected chi-square test when appropriate; p < 0.05 was considered significant. Patients and controls did not differ with respect to age, body mass (b.m.) and BSA. Resting energy expenditure (REE); after overnight fast, indirect calorime-
aim of the study was to evaluate the usefulness of endoscopic variceal ligation in the management of bleeding esophageal varices. Methods: 120 patients admitted to our hospital with acute esophageal variceal bleeding were randomized to receive sclerotherapy (EIS group) or band ligation (ELV group). All of them received treatment within 24 h of index bleeding. Sclerosant 1.5% Sotradecol and Steigmann-Goff ligator were used, respectively. Endoscopic variceal treatment was repeated at an interval of 2-3 weeks until varices obliterated.

Results: 113 of 119 patients undergoing EIS (96.6%) were treated successfully and 11 of 120 patients undergoing ELV (91.7%) were treated successfully. The time to re-bleeding was significantly different between the two groups (10.7 ± 5.4 months vs. 17.9 ± 6.2 months, respectively, p < 0.001).

Conclusions: Endoscopic variceal ligation causes significantly fewer complications than sclerotherapy. In addition, EVL prevents re-bleeding from esophageal varices more effectively than EIS does. However, higher frequency of ectopic varices bleeding may be encountered by EVL.
The following variables were recorded: liver function, amount of sclerosant, hemodynamic condition, hemorrhagic activity, duration of the procedure, units of transfused blood, hemorrhagic recurrence and mortality. An overall index of technical difficulty (IFT) was designed as the product: (number of injections required × viewing condition (1–3) × subjective feeling of technical difficulty (1–3)). Data were compared by t-student and chi-square tests.

**Results** - Both groups were similar on the following parameters: age, hemodynamic condition, degree of patient’s collaboration, activity of hem- orrhage and liver function. Although not significantly, more treated patients (14/33) had bled from gastric subcardiac varices than placebo patients did (7/30), (p = 0.1). Once the drug was administered, more treated patients ceased to bleed during the injection (21/33) than control patients (11/30) (p = 0.03). The amount of administered sclerosant was superior in the control group (medians 2 ml vs 9.4 ml respectively). The IFT was significa- ntly better in the treated group (3.5 vs 6.4, p = 0.03). On the contrary, no differences were registered in: units of transfused blood, recurrence of hemorrhage, mortality or time spent in the procedure.

**Conclusion** - The administration of a bolus of 250 mg of somatostatin results in an amelioration of the technical easiness of AS even though it does not seem to substantially change the final result of the procedure in skilled hands. This therapeutic complement could allow AS to be undertaken not only by highly skilled endoscopists, but also by gastroenterologists with a moderate expertise on therapeutic endoscopy.

### 1656 Congestive Gastropathy with Liver Cirrhosis

Nino Nicolaon, Teunen Ozeki, 1 Shigekuni Kono, Shinich Sugano, Yoshikichi Motojiya, Tametsune Ohkwa, Yasuo Shimizu. The Department of Gastroenterology, Ohmachi Hospital, Kitakyushu, Japan. 1 The 3rd Department of Internal Medicine, School of Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan

We have had gastrofibroscopy examinations of many patients with conge- stive gastropathy complicated to liver cirrhosis. However, reddening and edema of gastric mucosa were not found in cases with congestive gastropa- thy, but chronic gastritis were. Furthermore, the differential diagnosis as for the two diseases was considerably difficult. We tried to solve this problem and report a considerably successful diagnostic method using endoscopic tuloidine blue dye-spraying technique for congestive gastropathy. [Materials and Methods] Endoscopic tuloidine blue dye-spraying was carried out in 25 patients with congestive gastropathy complicated to liver cirrhosis and 30 patients with chronic gastritis. In gastrofibroscopy, the change metachroma- sia of color after spraying to the mucosa with reddening was observed and biopsy specimens of the same gastric piece were taken. Furthermore, gastric juice was collected by aspiration. Histological diagnosis was done by HE. Histological staining using tuloidine blue before and after choendojunction AB digestion was carried out. The measurement of chondrin sulfate in gastric juice was carried out using chondrininase digestion method. [Results] In endoscopic findings, diffuse reddening of mucosa in the greater curva- ture of body was stronger in congestive gastropathy than in chronic gastritis. Another characteristic features, edematous, pattern, was also observed and edema were often found in the greater curvature of body. As for spraying pattern in body of congestive gastropathy, mucosal blue colour pattern was 35% and the mixed pattern of blue and purple pattern was 60%. Histological staining of blue in specific area of chronic gastritis revealed staining metachromasia staining of goblet cells but after choendojunction AB digestion, metachromasia staining pattern almost diminished. In congestive gastropathy, metachromasia of goblet cells was very weak. Furthermore the amount of chondrinin sulfate A.B.C in gastric juice of congestive gastro- pathy was lower than that chronic gastritis (decrease about 40%). [Discuss- ion] Tuloidine blue is famous for metachromasia staining for chondrin sulfate. Patients with chronic gastritis more than 50 years old, have almost in- testinal metaplasia. Therefore, chondrin sulfate was secreted from goblet cells into gastric juice. However, in patients with congestive gastropathy the amount of chondrin sulfate in gastric juice is considerably less in congestive gastropathy than chronic gastritis, because the production of chondrin sulfate might be inhibited by congestion. [Conclusion] It was strongly sug- gestive that the gastric production of chondrin sulfate in congestive gastropa- thy might be inhibited because of congestion. The fact was also certified using endoscopic tuloidine blue spraying and useful for the diagnosis.

Before TIPS Child class was C in 2, B in 4 and A in 14 and no patient had a previous history of HE. All patients received lactulose therapy in the previous week and thereafter. The PSE index according to Coni was assessed before TIPS and after 7, 30, 90 days and then every 3 months. All episodes of HE which occurred at any time were assessed and recorded. 3 patients died be- fore the first month, 17 completed 3 months and 13 completed 6 months of follow up. During the first 3 months after TIPS 13/20 patients (65%) had one or more episodes of HE. HE reached grade III–V in 5 patients. PSE index was higher than 0.25 in at least 2 out of 3 patients (75%), indicating chronic HE. Several variables were tested but failed to correlate to the development of HE, these were age, etiology of liver disease, and the Child class, Coni index, ammonia levels, galactose elimination capacity and liver volume before TIPS, the stent diameter and the post-TIPS portal systemic gradient. The PSE index was significantly correlated to the mean velocity of blood flow into the stent at 4 weeks (r = 0.65; p < 0.02). Between 3 and 6 months of follow-up 4/13 patients (31%) had episodes of HE. In 3 of these patients a stable impairment of PSE index was found. In conclusion the in- cidence of episodic HE is high after TIPS but tends to drop after the first 3 months. A stable chronic elevation in the PSE index is still present in 23% of patients at 6 months although the alteration in mental state never exceeded grade I.

### 1658 Modifications in Liver Function After Transjugular Intrahepatic Portosystemic Shunt (TIPS)

R. Servi, M. Merli, O. Riggio, P. Meddi, F. Montagnese, M.ardi, G. Balducci, P. Rossi, L. Capocaccia. 2° Gastroenterologia, Radiologia Università "La Sapienza" di Roma, Italy; 1° Clin Chirurgica, Radiologia Università "La Sapienza" di Roma, Italy

This study describes the modifications in liver function in 20 cirrhotics (14 M, 6 F age 63 ± 7) who underwent TIPS for variceal bleeding (18 pts) or intraperitoneal ascites (2 pts). Child class, liver tests, and liver and spleen diameter (US measurements) were evaluated in all patients before and 2, 7, 30, 90 and 180 days after TIPS. The galactose elimination capacity (GEC) was performed before and after 6 months. 3 patients died within the first month, 17 completed 3 months and 13 completed 6 months of follow up. Results:

*p < 0.01 vs at least basal (paired T test)

In the first week jaundice developed in 6 patients (30%). In 3 patients this was due to hemolysis, with an increase in unconjugated bilirubin, a decrease in hemoglobin and the presence of schistocytes. A sharp transient increase in ALT (up to 800 U/L) and a reduction in Proth Act indicates that liver necrosis accompanied jaundice in at least 3 patients. One patient died after TIPS. Child score and bilirubin increased while liver diameter decreased compared to basal. These modifications were no longer evident 3 and 6 months later suggesting that liver function is not deteriorated by TIPS. Liver and spleen diameter were decreased after TIPS. These modifications are probably due to a reduced portal pressure and remained stable up to 6 months.

S. Siningo, L. Bolondi, S. Sofia, G. DiFebo, M. Miglioli, L. Barbara. Istituto di Clinica Medica e Gastroenterologia, Bologna, Italy

40% of the first VB episodes in cirrhotics occur within the first 6 mths of observation [J. Hepatol. 18 (3) 511-519, 1993]. This study was aimed to iden- tify the risk factors for early and late occurrence in most common variceal bleeding analysis. We studied 155 consecutive cirrhotics with varices and without pre- previous VB. At entry and at six months intervals the severity of liver disease and the appearance of varices were assessed according to the Child-Campbell classification and the JRSHPH endoscopic rules. During a mean f-u period of 25.0 (±17.5) mths 24% of the patients had VB, 38% did so within 6 mths. The VB rates were estimated at each 6 mths interval by life tables, Breslow (early differences) and Mantel-Cox test (overall differences). The table shows the available: variceal size (VS), cherry red spots (CRS), ascites, nutritional sta- tus were associated with the early and overall occurrence of VB through the study period. During f-u VS changed in 28% of F1, in 27% of F2 and in 6% of F3 varices. The actual overall rate of VB for those that ultimately had F1, F2 and F3 was: 3%, 20%, 70%. The cumulative rate of early VB (<6 mths) was 50% in F3 varices present from entry and 16% in F3 varices developed

during f-u (P = 0.04); 8% in F2 present from entry and 0% in those developed during f-u (P = ns). The figures for late (>6 mths) VF were 67% for F3 from entry and 70% for F3 during FU (P = ns), 50% for F2 at entry and 34% for F2 during f-u (P = ns). Conclusions: (1) By univariate analysis V5 seems to be the most important variable in predicting the first VF. (2) Different treatment strategies should be used for F2 and F3 varices. (3) Regular endoscopic f-u is needed to improve the prediction criteria for the first VF.

1660 Non-Shunt Surgery for Bleeding Varices. 12 Years Experience
Ahmed Sultan, Nabil El-Ghawely, Omar Faty, Mohamed Abdel Wahab, Mohsen El-Barbary, Nadim El-Hak, Gamal El-Ebiedy, Farouk Ezazz, Gastroenterology Center, Mansoura, Egypt

During the period from 1979 to 1991, 596 case of splenectomy and devascularisation were done electively for portal hypertension patients with history of moderate, massive or repeated attacks of haematemesis and or melena (elective group). 41 case of the same procedure were done for patients with acute varical hemorrhage which failed to be controlled with emergency sclerotherapy (emergency group). All patients were Child A & B. The mean age of the patients were 34.8 ± 10.5. Male to female ratio was 9:1. Complete liver functions, kidney functions, complete blood picture and upper gastro intestinal endoscopy were done for all patients. Needle liver biopsy was done for 554 patients from the elective group. The pathology was schistosomal in 36.8%, mixed schistosomal and cirrhosis in 33.4% and non-schistosomal in 29.8%. The operation was done by the technique of Hassan (1962). Splenectomy & devascularisation gives immediate control of bleeding in 92.7% of emergency group. Hospital Mortality was 3.8% & 2.2% in both groups respectively. All patients were followed up for 50 ± 31 month. Recurrent rebleeding was 15.3% & 17% in both groups respectively. Encephalopathy developed in 2.5% in both groups. Late mortality was 8.55% & 9.7% in both groups respectively. We concluded that splenectomy & devascularisation was able to control bleeding both in emergency and elective cases with acceptable recurrence rate of rebleeding and low rate of encephalopathy.

1661 Portal Haemodynamic Response to a Very Low-Dose Nitroglycerin in Cirrhosis

A low dose of nitroglycerin (NTG) predominantly dilates the venous system. Portal haemodynamic responses to a very low dose of NTG were studied in patients with portal hypertension and variceal bleeding, compared with those to an usual dose of coronary heart disease. A 0.15 mg of NTG was sublingually given to 10 patients (LDG) and a 0.3 mg to another 10 patients (UDG). Haemodynamic measurements under the hepatic and right cardiac catheterization were carried out before and 5 min after NTG administration. Wedged hepatic venous pressure (WHVP) reduced after NTG by 8%; p < 0.01 in LDG, and by 15%; p < 0.01 in UDG. Hepatic blood flow with ICG did not change in both groups. In LDG, axysos blood flow (AZF) did not change in contrast to a significant decrease by 11%: p < 0.05 in LDG. Mean arterial pressure fell by 4%; p < 0.05 in LDG and by 15%; p < 0.01 in UDG. Cardiac index did not change in LDG, but it decreased by 12%; p = 0.05 in UDG. In LDG as well as UDG, mean pulmonary arterial pressure and pulmonary capillary wedge pressure significantly fell and the magnitude of these falls in both groups were same. In UDG, a correlation between changes in WHVP and AZF (r = 0.7, p < 0.05) was observed. This suggested that splanchic vasocconstriction mediated by high-pressure, rather than low-pressure, baroreceptor reflex mainly contributed to a decrease in portal venous blood flow, resulting in a WHVP reduction. Whereas, a slight but significant fall of WHVP induced by a very low dose of nitroglycerin might be due to venuodilation including hepatic vascular bed.

1662 Blood Flow and Intestinal Transport in Chronic Biliary Anastomoses
A.P. Oettinger, M. Polivoda, G. Aft, V. Schumpelick. Joint Institute for Surgical Research, Moscow, Aachen

 Aim of the study: Disadvantages of Roux-Y biliary anastomoses are duodenal bypass of bile and the lack of an endoscopic access to the biliary anastomosis. Recently hepatico-jejunoduodenal interposition (HJD-IP) has been propagated to overcome these problems. The aim of our study was to investigate the changes in bile flow in these procedures.

Methods: 15 cholecystectomized mongrel dogs were operated as follows: RY-BA using a 30 cm jejunal loop (n = 5), HJD-IP with a 15 cm jejunal segment (n = 5), no additional procedure (control-group, n = 5). Four months postoperatively all animals underwent a hepato-biliary scintigraphy using 99mTc Hepatobiliary® and a Picker Dyna-Camera-4. Regions of interest (ROI) were liver, bile ducts, anastomotic side of the jejunal loop, distal part of the RY-loop, Treitz ligament, gastric antrum and cecum.

Results: Hepatic uptake of the tracer, that means time of max. activity (Tm) in the liver field was delayed in RY-BA (13.2 min) in comparison to the controls (9.0 min). This delay was even more pronounced in HJD-IP (23.0 min, p < 0.05). Tm in the extrahepatic bile ducts showed a similar delay in RY-BA and HJD-IP (40.0–42.6 min versus 20.0 min for the controls). Initial evacuation into the loop (T1) was also similar in both biliary anastomoses (33.2–33.5 min) but maximum of activity (Tm) appeared in the proximal part of BA more late (71.2 min) than in the HJD-IP group (58.5 min). On the other hand percentage of applied activity in BA loops (50.1%) exceeded the value in the HJD-IP loop (41.8%) indicating circulation of bile in the RY-BA loop. Transport through the Roux-Y loop lasted as long as bile flow from the HJD-IP loop to Treitz ligament. Ti at the ileo-cecal region showed a similar delay in both groups (123.4–127.0 min) compared with the controls (95.0 min). Bile reflux into the gastric antrum was a regular phenomenon in HJD-IP but not in RY-BA animals.

Conclusion: Consequences of chronic HJD-IP in dogs are a significant disturbance of hepatic bile uptake and recurrent duodenogastric bile reflux. RY-BA show a more normal liver function but a pronounced stasis of bile in the Roux-Y loop. Chronic hepatic inflammation following HJD-IP and motility disorders in the Roux-loop in RY-BA may be the underlying pathophysiological mechanisms.

1663 The Mechanism of Pentagastrin Related Inhibition of Small Bowel Bioelectric Activity – An Experimental Study on the Rat
A.P. Oettinger, K.G. Krishnan, G. Aft, Ch. Toens, M. Polivoda. Joint Institute for Surgical Research - Moscow/Aachen

It has been shown that large doses of Pentagastrin (PG, 0.06-0.1 mg/kg BW) brings about the inhibition of small bowel bioelectric activity (SBEA), which is suspected to be caused by a decrease in blood flow due to vasoconstriction. Our aim was to investigate the mechanism of action of PG and the correlation of its effects with the O2 balance in the bowel, which can be of value as an important prognostic sign in various surgical conditions of the intestine, especially in small bowel transplantation.

Methods: The study was conducted in 15 murine small bowels in vivo and in vitro. The latter in conditions of bowel perfusion in oxygenated (pO2 = 450 mm Hg) and unoxgenated (pO2 = 100 mm Hg) Krebs solution (KES) at 37°C. Under Toentper nal narcosis in 7 rats (control group) the native SBEA and its reaction to intravenous PG administration (0.06 mg/kg BW) were registered with silver bipolar electrodes of the clip type. Then 5 cm of the central ileum was isolated and placed in unoxgenated KES. The SBEA and the PG effect were recorded. Afterwards the bowel was transferred to oxygenated KES and the same procedure was repeated. 8 rats (test group) were saturated with an hypoxiant substance (carotene like substance, 5 mg/kg BW) and by oxygenated administration 30 min prior to laparotomy and procedures were repeated as mentioned above.

Results: In vivo the SBEA readily vanished to a straight line on PG administration in the control group. This effect was absent in the test group. In hypoxia in vitro the control group again showed a vanishing tendency of the SBEA on PG, while the test group documented no change. In normoxia in vitro the control group showed a decrease in the amplitude and the frequency parameters of the SBEA on PG, but not to the extent of vanishing. The test group, here, recorded an increase in the SBEA values on PG.

Conclusion: We conclude that the reaction of the SBEA to high doses of PG is related to the direct action of PG on the smooth musculature and activation of the intramural neural elements through the decrease in oxygen uptake by the tissue. We suppose that a "high-dose PG test" may serve as an intraoperative test of the bowel in surgical interventions and transplantation.
Portal hypertension
