LETTERS TO THE EDITOR

Cerebral fibre and rectal epithelial cell proliferation: a possible link with duodenal ulceration

EDITOR,—It is interesting that Macrae et al (Gut 1997;41:239–45) found that unprocessed wheat bran had a greater effect than processed bran or oat bran on the reduction of labelled cells in the top two fifths of rectal epithelial crypts. There is evidence that wheat bran may have effects on other mucosal surfaces, particularly that of the duodenum. The prevalence of duodenal ulceration is lower in India than in the polished rice eating areas of the Punjab than in the polished rice eating areas of the South.1,2 Our experimental work on several animal models has shown that wheat bran is protective against duodenal ulceration and that this protection is linked with its lipid content.1,3 The evidence so far suggests that this effect may be related to a unique combination of lipids in certain cereal fibres and not to a particular type of fibre.

“Golf ball liver”: a cause of chronic hepatitis?

EDITOR,—We were interested to read the letter by Johnston et al, further to our report in the July issue, which appears to document a case of chronic hepatitis possibly caused by the patient’s habit of licking his golf balls. It appears that the habit of golf ball licking is certainly not confined to Ireland and appears, at least anecdotally, to be a relatively common practice. Given this widespread practice and the now documented ability of 2,4-D to cause an acute hepatitis, it is certainly within the realms of possibility that a chronic hepatitis may also result from chronic exposure to 2,4-D.

However, the case reported by Johnston et al requires some clarification. It would be helpful to know whether any cosinophils were seen on the liver biopsy sample, and if not readily seen on straightforward stains then possibly mononuclear markers such as EG1 or V tensor golfer for many years and licks his golf balls during practice. On investigations as indicated above have failed to reveal a specific cause for his chronic hepatitis and cirrhosis. In view of the recent case report (Gut 1997;40:687–8) relating acute hepatitis to inadvertent ingestion of 2,4-D, it is proposed that ingestion of this substance by golfers may also lead to chronic hepatitis and even cirrhosis as in the case of this young man with no other apparent cause for his liver disease. The results of abstention from licking his golf balls are eagerly anticipated.

EDITOR,—We were interested to read the letter by Johnston et al, further to our report in the July issue, which appears to document a case of chronic hepatitis possibly caused by the patient’s habit of licking his golf balls. It appears that the habit of golf ball licking is certainly not confined to Ireland and appears, at least anecdotally, to be a relatively common practice. Given this widespread practice and the now documented ability of 2,4-D to cause an acute hepatitis, it is certainly within the realms of possibility that a chronic hepatitis may also result from chronic exposure to 2,4-D.

However, the case reported by Johnston et al requires some clarification. It would be helpful to know whether any cosinophils were seen on the liver biopsy sample, and if not readily seen on straightforward stains then possibly mononuclear markers such as EG1 or EG2 could be used. This is of importance as if chronic golf ball liver exists then it raises the question of whether it is a toxic phenomenon or a chronic allergic/hypersensitivity process. It would also be of interest to know whether the authors documented that 2,4-D was actually being spread on the patient’s golf course. How long had the patient been licking his golf balls prior to the initial illness in 1992, and had the chemicals used on the patient’s golf course changed in or around this time.

There was any temporal relation between the patient’s symptoms and the times of heaviest concentration of 2,4-D on the golf course or the frequency of this patient’s golfing excursions? We await with interest any further developments.

Mesalazine as a maintenance treatment in Crohn’s disease

EDITOR,—We read with interest the occasional viewpoint by Sahmoud and Mary (Gut 1997;40:284–5). As is too often the case in such reviews, the authors have failed to identify all of the relevant literature pertinent to the topic: the maintenance of remission or prevention of recurrence of Crohn’s disease. For example, with regard to azathioprine, rather than two trials of treatment, actually six trials (including the NCCDS Parts I and II) have been published. The results were summarised recently in a metaanalysis of these trials. However, this systematic review concluded that the common odds ratio for maintaining remission for azathioprine treated patients was 2.3 (95% confidence interval (CI) 1.8 to 2.9) and that there was a relation between the cumulative dose of azathioprine prescribed and the response. Azathioprine should be considered an option for maintenance treatment.

The authors have also selectively reviewed the literature with regard to mesalazine. Turning to the postoperative population, a large North American trial which identified a benefit for mesalazine for prevention of recurrence has been ignored, as well as trials which used endoscopic recurrence as a surrogate end point. A second systematic review, published in the same year as that of Messori et al reached similar conclusions and has been updated recently.1 Patients who received mesalazine were more likely to remain in remission compared with those on placebo. The relative risk of relapse was 0.63 (95% CI 0.50 to 0.79) for patients receiving mesalazine as compared with placebo.

We agree with the authors that additional studies are required and that differences in patient selection provides a likely explanation for differences in response. Identification of patients at higher risk of relapse might result in more cost effective treatment. Results have been conflicting with regard to clinical attributes of disease activity. While recognising that an analysis based on individual patient data might provide additional insight, the lack of consistent biological markers for high risk of recurrence (for example, permeability studies) in previous studies might make the approach irrelevant.

The issue as to whether or not to initiate maintenance treatment with either mesala-
zine or azathioprine remains a matter for discussion between patient and physician.

Emergency admission to hospital for colitis due to inflammatory bowel disease

EDITOR.—We were interested to read the study by Evans et al (Gut 1997;40:619–22) as we have recently reported a prospective study of colitis drawing similar conclusions.1 Our study, however, showed a much stronger association. Forty five of 62 (72.4%) new cases of colitis were taking non-steroidal anti-inflammatory drugs (NSAIDs) or salicylates suggesting a cause/effect relationship. In these patients histological differentiation from ulcerative colitis “due to inflammatory bowel disease” was not possible in the majority of cases. However, in a minority (30%) subsequent independent histological assessment revealed some of the criteria of NSAID colitis.2 These criteria of NSAID colitis had not been established at the time of the study (1989–93) by Evans et al. Thus the interpretation of their cases as Crohn’s or ulcerative colitis according to the criteria of Lennard-Jones3 may not be entirely valid.

In our opinion future epidemiological studies of the possible association of colitis and drugs need standardised histopathological review, preferably by a pathologist blinded to the drug history of the patient, which must be stringently determined by the referring clinician. It is probable that many patients classified as having “colitis due to inflammatory bowel disease” will in fact be suffering from colitis induced by NSAIDs. These drugs may be some of the most important environmental factors in the pathogenesis of ulcerative colitis according to the criteria of the study (1989–93) by Evans et al. However, our group of cases (who are ill) often recall past exposure to NSAIDs is associated with colitis. Compared with recall bias, we judge this to be a small effect when compared with recall bias.

Gleeson and Warren suggest that the difference between the two studies can be explained by differences in the spectrum of disease studied. In terms of severity, this might be true. Our cases were all severe enough to warrant hospitalisation. It is possible that milder colitis might be more strongly associated with exposure to NSAIDs. Gleeson and Warren suggest that NSAID colitis might be a more specific condition. Nearly all of our cases had firm diagnoses of ulcerative colitis or Crohn’s disease. It is possible that a specific NSAID induced, less severe form of colitis would not be detected in a study of this size.

In our study incident colitis was quite strongly associated with current NSAID exposure (odds ratio (OR) 2.96) whereas non-incident colitis was not (OR 1.16). Causal inference is possible explanation of an association. Our study was carried out to clarify the “signal” of possible NSAID associated colitis suggested by case reports. It seems illogical to suggest that we should then use case report evidence to strengthen our causality inference. Case reports provide a low standard of evidence of causality. They are anecdotes and the plural of anecdote is not data.

Arguments for a causal association depend upon the strength of the association, presence of biological gradient (dose response), consistency of the findings (lots of studies showing the same), and biological plausibility (a mechanism). We are further towards a causal association than before these studies were performed. However, we still have a lot of work to do before causality can be accepted.

The important point of our paper is that exposure to NSAIDs is associated with a severe adverse event, namely hospitalisation for incident (Crohn’s and ulcerative) colitis. A milder, specific, NSAID colitis morbidity. This is an attractive hypothesis which should be tested using epidemiological studies. We would be happy to collaborate with such a venture.

Reply

EDITOR.—Gleeson and Warren agree with the conclusions of our recent paper, that exposure to NSAIDs is associated with colitis. Where they disagree is on the strength of the association between exposure and colitis. Unfortunately, the abstract of the study they cite contains insufficient data to make a meaningful comparison between the two studies.1 However, one possible reason for the difference is that the control group (513 attendees at a minor injuries clinic), recalled less prior NSAID exposure than their cases. Cases (who are ill) often recall past exposure more than controls (who are not ill). Recall bias is a common and difficult problem in epidemiology. The population based dispensed prescribing data we used as our measure of exposure did not suffer from this bias.

We agree that the NSAIDs aspirin and ibuprofen which are available in low dose over-the-counter formulas, might have resulted in some exposure misclassification, but we judge this to be a small effect when compared with recall bias.

Gleeson and Warren suggest that the difference between the two studies can be explained by differences in the spectrum of disease studied. In terms of severity, this might be true. Our cases were all severe enough to warrant hospitalisation. It is possible that milder colitis might be more strongly associated with exposure to NSAIDs. Surveillance of the duodenum in patients with familial adenomatous polyposis

EDITOR.—We compliment Vasan et al (Gut 1996;40:716–19) on their attempt to quantify the benefit of surveillance of the duodenum in patients with familial adenomatous polyposis (FAP). We should like to make the following points.

The St Mark’s study2 is not strictly comparable to the Scandinavian study in that in the former results are based on the use of a side-viewing endoscope to focus particularly on the high risk periamputal area, whereas the Scandinavian study used forward viewing endoscopes only.

Vasan et al state that pancreaticoduodenectomy has substantial morbidity and mortality, this statement contradicts another within the body of the text referring to the decline in mortality from this operation over the past decade. It would be fair to say that the operation has the potential for substantial morbidity and mortality. However, this potential has not been fulfilled, especially in the context of a performance of a pylorus-sparing pancreaticoduodenectomy (E Tret and C Penna, Hôpital St Antoine, Paris, France, personal communication), together with encouraging results with regard to the lack of recurrence of duodenal adenomas.

We would suggest that a baseline screening examination be done before the age of 30. This might be done at the time of colectomy. This may be particularly worthwhile in those patients with a family history of duodenal cancer where such an examination would hopefully also reassure them.

There is additional evidence to that cited in favour of the existence of the adenoma–carcinoma sequence in the duodenum.3 For example, adenomas were found in or adjacent to duodenal carcinoma in 8% (38/45) of patients with FAP.

We agree that the results of surveillance should be collected in a uniform manner at a central registry. In this way the quoted criteria for surveillance, screening, namely the natural history of duodenal adenomas, the

We regret that our comments on the Spigelman classification gave the impression that we dislike the name of this classification. On the contrary, we believe that the classification proposed by Spigelman is very useful and fully deserves his name.

BOOK REVIEWS

Gastro-oesophageal reflux disease (GORD) can now rightly be regarded as the English disease as its prevalence here exceeds that of any other country.

This book is a response to the “swelling chorus of acclamation” relating to the place of minimally invasive surgery for the treatment of this condition and actually has a great deal to offer for anyone involved in the management of reflux patients.

In the 32 short essays there are some very important and highly relevant questions about GORD and an attempt to answer them. It is sometimes reassuring to know that despite a very informed discussion and sound reasoning, even the experts have uncertainties about, for example, Barrett’s surveillance and how to manage the very exciting concept of the ultra-short oesophagus.

The reappraisal of the diagnostic assessment of GORD is both timely and very helpful. Any attempt to abolish “equivocal oesophagitis” and to reduce the interobserver variation in this rather important and specific finding is, of course, welcome. There is no doubt that the major parts of the book are about when, how and who should do a “lap-wrap”. We are told that from the health economics point of view there is a break even point at six years when one compares a laparoscopic Nissen versus long term omeprazole. When one considers an open Nissen this break even point is not reached for 10 years. On the other hand in the USA, despite the existence of 40,000 Board Certified Surgeons there are probably only a small group of suitably trained surgical experts who can safely perform a laparoscopic fundoplication.

Several of the chapters delve into the technical details of laparoscopic anti-reflux surgery and the surgeons will certainly welcome the discussions about the importance of mobilising short gastric vessels, the use of a Bougie, the length of the wrap as well as the place of a partial (Toupet) fundoplication. This book will also find a very welcome place with those who occasionally have to manage those unfortunate dysphagic patients after surgery and hopefully will approve the recommendation of a wait and see policy. A very sensible algorithm is presented for coping with this rather distressing complication. Perhaps an equally complexing problem are those with recurrent reflux after surgery, and it is particularly refreshing to have a frank discussion about the management of this group, emphasising the potential morbidity and even mortality of surgery in this particular scenario.

This book is about wrap versus wrap. It is highly informative, at times entertaining, and will be of great value to those who are either in or hovering on the edge of the expanding field of laparoscopic anti-reflux surgery.

J M MORTENSEN

All hepatologists and right-thinking physicians will be well aware that the liver is not only the largest internal organ but also the most important. In systemic diseases, the liver is often affected and liver function disturbed; conversely, primary liver disease can affect every other organ system. While most of the major medical and hepatological textbooks have sections on the liver in systemic disease, this inevitably tends to be rather a rag-bag of topics. The laudable purpose of this book is “to provide a review of the hepatic manifestations occurring or resulting from diseases of other organs.” To this end, Professor Gitlin has brought together a galaxy of eminent hepatologists from North America with a few non-hepatologists to produce a well-presented and extensively illustrated book, and has largely succeeded in his aim.

Reply

Editor.—We thank Drs Spigelman and Phillips for their remarks. We agree that the St Mark’s study and the Scandinavian study are similar in the detection rate of stage IV disease and are usually a marker of advanced disease, whilst we prefer to make a decision on the basis of experience.

The incentive for testing novel treatments occurring or resulting from diseases of other organs.

The disadvantage of recommending a baseline duodenoscopy before the age of 30 is that if abnormalities are found, most physicians will decide to continue (frequent) examinations, thereby imposing an additional burden on the patient. Although exceptions can be made for patients seeking reassurance, we prefer to make a decision on the basis of the natural history of the disease, which indicates that duodenal cancer before 30 years of age is extremely rare.

Availability of curative treatment and evidence that this treatment leads to improved prognosis can be assessed. Without surveillance of these individuals, the natural history will remain unknown. Treatments will not be able to be instituted until symptoms, which are usually a marker of advanced disease, occur. The incentive for testing novel treatments, such as Sulindac and its derivatives, COX 2 agents, photodynamic laser therapy, antacid administration or gene therapy, COX 2 agents, photodynamic laser therapy, antacid administration or gene therapy, would not be great.

Finally, a point of personal sensitivity. Vasn et al’s reference to the “so-called” Spigelman classification neglects to say that this classification was “called-so” in the literature by the Scandinavian group itself! When we remain in favour of eponymous labelling of conditions and are indeed gratified to see that these authors have adopted the term Bussey–Gardner polyposis, the stimulus for labelling the classification of severity of upper gastrointestinal disease in FAP did not come from the St Mark’s group.

A SPigelman
R Phillips
St Mark’s Hospital, London, UK.

On the contrary, we believe that the Spigelman classification gave the impression that we dislike the name of this classification. On the contrary, we believe that the classification proposed by Spigelman is very useful and fully deserves his name.

We do not believe that our statements on the association with pancreateoduodenectomy are contradictory, as we still consider a mortality of 5% to be substantial, especially if this surgical procedure is performed in a relatively young patient with a disease that is potentially malignant but still benign (stage IV duodenal polyposis).

An important issue which was not mentioned in our manuscript is that recent studies indicate that mortality is significantly higher in hospitals with limited experience (fewer than 50 procedures per year).

We would therefore like to emphasise that such procedures should be performed at centres in which experience is available.

The disadvantage of recommending a baseline duodenoscopy before the age of 30 is that if abnormalities are found, most physicians will decide to continue (frequent) examinations, thereby imposing an additional burden on the patient. Although exceptions can be made for patients seeking reassurance, we prefer to make a decision on the basis of the natural history of the disease, which indicates that duodenal cancer before 30 years of age is extremely rare.

W J Owen

Since its introduction in 1989, anal ultrasonography has revolutionised the assessment of anal sphincter injuries and incontinence and allows the identification of the affected muscle layers. This book is a response to the “swelling field of laparoscopic anti-reflux surgery. Clive Bartram, the father of anal endoscopyography, with Alan Walker, who occasionally have to manage those with this rather distressing complication. Per-
There are 14 chapters which encompass the major body systems. Although this volume will be used as a reference source, there are several chapters which make compelling reading: those on the liver in diabetes and hyperlipidaemia, nutritional and haematological disorders, and sarcoidosis (which is rather a review of hepatic granulomas) were especially enjoyable to read. There are a few puzzling omissions: for example, I could find no mention in the index of the appropriate chapters any discussion of the liver involvement in coeliac disease; iron overload is discussed briefly in the context of thalassaemia but no mention is made of liver involvement in coeliac disease; iron are a few puzzling omissions: for example, I haematological disorders, and sarcoidosis is the major body systems. Although this volume will be used as a reference source, those with an established interest in the field, perinatal nutrition, nutritional pathophysiology are well covered in the first half; and perinatal nutrition, nutritional pathophysiology are well covered in the first half; and perinatal nutrition, nutritional pathophysiology are well covered in the first half; and perinatal nutrition, nutritional pathophysiology are well covered in the first half; and perinatal nutrition, nutritional pathophysiology are well covered in the first half; and perinatal nutrition, nutritional pathophysiology are well covered in the first half; and perinatal nutrition, nutritional pathophysiology are well covered in the first half; and perinatal nutrition, nutritional pathophysiology are well covered in the first half; and perinatal nutrition, nutritional pathophysiology are well covered in the first half; and perinatal nutrition, nutritional pathophysiology are well covered in the first half; and per

health in the past decade, the reduced mortality associated with reversal of mild vitamin A deficiency. The only reference to kwashiorkor is in the chapter on nutritional anaemias, and we could find little on protein-energy malnutrition in the developing world, even in the chapter devoted to malnutrition in hospitalised children. However, three chapters emphasise the importance of human milk and breast feeding to infant nutrition, and the amount of research that has gone into this field. It is encouraging to see the practical “Approach to breast-feeding” chapter included in a book otherwise largely concerned with science and disease.

The focus of textbooks has moved away from “nutrients” towards “nutritional support”, recognising the critical part malnutrition plays in chronic childhood diseases. In considering specific diseases, the book recognises that the efficacy of nutritional support is proved in some areas (for example, Crohn’s disease, short bowel syndrome, and renal failure), but avoids discussion of a more controversial and difficult topic, nutritional support in congenital heart disease. The final section includes chapters on parenteral and enteral nutrition.

For the specialist in paediatric nutrition this book compares well with its competitors, and in its second edition it is strong in clinical application. However, with its international authorship and presumed international readership it is a pity that there is not more on global problems in paediatric nutrition, which would broaden its appeal. Nevertheless, at a time when paediatric nutrition is close to standing alone as a distinct subspecialty, this book will find a secure place as a standard text for students, trainees, teachers, and practising paediatricians.

NOTES

Course in Postgraduate Gastroenterology

A Course in Postgraduate Gastroenterology will be held in Oxford, UK, on 4-7 January 1998. This course has been designed for consultants and registrars, including those who do not specialise in gastroenterology. Topics will include:

- Liver disease
- Colonic neoplasia
- Acute pancreatitis
- Osteoporosis, arthritis and GI disease
- Food allergy and intolerance.

Course fee £200 ($330). Board and accommodation are available at Wadham College at extra cost. Six bursaries will be available for applicants training in gastroenterology or in research posts at British hospitals. Further information from: Dr DP Jewell, Gastroenterology Unit, Radcliffe Infirmary, Woodstock Road, Oxford OX2 6HE.

Colorectal Disease in 1998

The 9th Annual Colorectal Disease in 1998: An International Exchange of Medical and Surgical Concepts will be held at Marriott’s Harbour Beach Resort, Port Lauderdale, Florida, USA, from 19 to 21 February 1998. Further information from: Cleveland Clinic Florida, Department of Education, 2950 West Cypress Creek Road, Port Lauderdale, FL 33309-1743, USA; Fax: 954 978 5530; Other: 800 359 5101, ext 5056; Local/ international: 954 978 5056; email: jagele@ccsmtp.ccf.org.

6th Southeast European Congress of Paediatric Surgery: Short Bowel Syndrome

The 6th Southeast European Congress of Paediatric Surgery: Short Bowel Syndrome will be held in Graz, Austria, on 22-23 May 1998. Further information from: Dr Günther Schimpfl, Department of Paediatric Surgery, Auenbruggerplatz 34, A-8036 LKH-Graz, Austria. Tel: +43 316 385 3762; Fax: +43 316 385 3775.

9th British Association of Day Surgery Annual Scientific Meeting

The 9th British Association of Day Surgery Annual Scientific Meeting and Exhibition will be held at the Harrogate International Centre, Harrogate, UK, on 4-6 June 1998. Further information from: Kite Communications, The Silk Mill House, 196 Huddersfield Road, Meltham, West Yorkshire HD9 1AP, UK. Tel: 01484 854575; Fax: 01484 854 576; email: info@kitecomm.co.uk.

9th International Symposium on Cells of the Hepatic Sinusoid

The 9th International Symposium on Cells of the Hepatic Sinusoid will be held in Christchurch, New Zealand, from 27 September to 1 October 1998. Further information from: Professor Robin Fraser, Christchurch School of Medicine, PO Box 4345, Christchurch 8001, New Zealand. Tel: +64 3 3640 587; Fax: +64 3 3640 593; email: grogers@chmeds.ac.nz.

Growth Factors and Nutrients in Intestinal Health and Disease

An International Symposium on Growth Factors and Nutrients in Intestinal Health and Disease will be held at the Rihga Royal Hotel, Osaka, Japan, from 31 October to 3 November 1998. Further information from: Kinya Sando, MD, Department of Pediatric Surgery, Osaka University Medical School, 2-2 Yamadaoka, Suita, Osaka 565, Japan.
