LETTERS TO THE EDITOR

Is needle biopsy of the liver necessary to diagnose HCC?

EDITOR,—Schotman and colleagues (Gut 1999;45:626–7) reported a patient with subcutaneous seeding of hepatocellular carcinoma (HCC) after percutaneous needle biopsy together with a review of 14 similar cases and correctly outlined the necessity for a critical evaluation of the role of needle biopsy in resectable HCC. 1,2

We agree with their conclusion, namely that if it is not possible to diagnose HCC by other means (namely increased a fetoprotein (AFP) concentrations, spiral computed tomography (CT), magnetic resonance imaging); in these cases a single pass with a large needle (18 gauge) may be preferable to multiple passes with smaller calibre needles; (ii) needle biopsies are not indicated to confirm HCC in patients suitable for liver transplantation; and (iii) the entire needle tract should be resected at surgery for the primary tumour. This has been important in other skin recurrences, namely those after laparoscopic cholecystectomy for undiagnosed gall bladder carcinoma. 3,4

However, we have some questions and comments concerning the reported case. Firstly, why did the authors perform tumour biopsy in a 30 year old woman with hepatitis B liver cirrhosis and raised serum AFP, showing a 2 cm diameter subcapsular nodule in segment V and two additional satellite lesions in the same segment? Adequate imaging procedures were already available four years ago. In fact, the patient had percutaneous liver biopsy together with an informative diagnostic procedure such as spiral CT. In addition, subcapsular liver lesions are known to give a high rate of both subcutaneous recurrence and intraperitoneal subduralpragmatic seeding. 5 Therefore, in contrast with recurrence after laparoscopic surgery which mostly cluster around abdominal port tracts, 6 simple removal of the needle tract could not be sufficient to prevent the side effects of percutaneous liver biopsy. Secondly, why did they perform right hepatectomy in a cirrhotic liver rather than segment V segmentectomy? The latter could be a similar adequate procedure while preserving better residual liver function.

The authors should be congratulated for focusing once again on a very important question (to biopsy or not to biopsy liver nodules in suspected HCC in the present era of highly effective imaging) and for their collection of 15 cases, which is obviously an underestimation of what occurs in practice and is currently observed in many transplantation centres. However, their message for the reader should be clearer as there is an apparent contradiction between what they state and what they actually did.

EDITOR,—We read with great interest the letter of Cetta et al in which they discussed our case (Gut 1999;45:626–7) of subcutaneous seeding of a hepatocellular carcinoma (HCC) after percutaneous needle biopsy. Firstly, they state that a needle biopsy was not indicated in the case presented. It must be stated that the biopsy was performed elsewhere before the patient was admitted to our hospital. Secondly, they suggest that a smaller partial hepatectomy might have been sufficient to treat the HCC in this 30 year old woman with hepatitis B liver cirrhosis. In the case presented there was no deterioration in liver function or impaired functional reserve after resection. The postoperative course was uneventful.

In general, we agree with the opinion to limit resection as far as possible and presently we would perform a segmentectomy.

Management of gastric fundal varices associated with a gastrorenal shunt

EDITOR,—We read with great interest the article by Jalan and colleagues (Gut 2000;46:578–81) on the clinical position of transjugular intrahepatic portosystemic stent-shunt (TIPSS). This procedure is a useful method of reducing portal pressure by creating a portosystemic shunt in the liver. They suggested that TIPSS can be a successful treatment option for controlling gastric fundal varices (FV) unresponsive to pharmacological and endoscopic therapy. However, Sanyal et al reported that TIPSS was ineffective for FV associated with a large gastrorenal shunt, even when the hepatic venous pressure gradient falls below the critical bleeding threshold of 12 mm Hg. 7

The behaviour of varices at different sites seems to differ. Therefore, FV should be treated on the basis of their hemodynamics.

Reply

The data in the literature do not support either of the points of view that have been suggested by Matsumoto et al. Although data on the use of B-RTO for the treatment of fundal varices are exciting, we look forward to randomised controlled clinical trials comparing TIPSS with B-RTO.

The science, economics, and effectiveness of combination therapy for hepatitis C

EDITOR,—No one affected by hepatitis C virus (HCV) will question Professor Dush- eiko’s insistence on the importance of effective therapy for HCV and the funding to meet them (Gut 2000;47:159–61). With research and clinical evidence pointing to a prevalence of HCV infection far in excess of human immunodeficiency virus (HIV), the issue has now become urgent. Patients and clinicians alike will await the forthcoming NICE appraisal in the hope it recommends in favour of allocating sufficient resources to cover treatment costs for those most in need and best able to benefit.

However, while a positive response will be welcome it will also uncover issues that have still to be fully addressed. These centre on who will be selected for treatment and the effects of the treatment itself.

Regarding the first issue there remains a debate around who will benefit most from treatment. The best way to assess outcome is in terms of genotyping, age, duration of viraemia, extent of liver damage, and other complicating factors, such as continued drug and alcohol abuse. While there may be some validity to such categorisations, they are not at all absolute and can demoralise patients. Nevertheless, and leaving such considerations aside, if HCV infection is as widespread as some clinicians anticipate, it would be unrealistic to believe that a treatment will be available to treat everyone. This means that some form of treatment selection will need to be adopted. Should this occur, the question remains as to how clinicians will make choices and what criteria they will use. Furthermore, will protocols be in place to govern these criteria to ensure they are standardised nationwide?

Although Dushko et al cite the potential priority given by the NHS to combination treatment as the salient issue, this needs to be addressed in conjunction with the equally important matter of who should receive this treatment. Notwithstanding any controversy over whether combination therapy, or both, is a factor that needs to be implicated in discussions around HCV, but which clinicians tend to underestimate, is patient tolerance and possible lingering effects of therapy. Although there seems to be far a fairly clear cut case in favour of the greater efficacy of combination treatment, it is harder for patients to tolerate than monotherapy with IFN, particularly when taken over 48 weeks. Despite this, it seems to state that the 20% (approximately) of patients who discontinue therapy before 48 weeks usually do so because of “insomnia, depression, irritability, or anaemia”. This would seem to suggest that those involved with the intensity of side effects from combination therapy, which can be equally as debilitating for some patients as those of chemotherapy. In addition, the sequelae of treatment can sometimes linger for months following its cessation.

Given the potential severity of side effects, many patients with mild HCV have resisted conventional treatment methods and opted instead to try to minimise disease progression by recourse to alternative therapies. A recent nationwide trial offered to patients with mild HCV failed to recruit anywhere near its target numbers. This would suggest that those with less risk of progressive disease, and therefore less motivation to seek a cure, are more resistant to therapeutic intervention.

Notwithstanding the obvious factor of the greater and more urgent need for treatment for patients with progressive disease following HCV infection, perhaps this trend in mild HCV sufferers might offer some insight as to how patients sometimes choose for themselves—suggested to be those involved with the healthcare of HCV patients an indicator of how best to prioritise treatment should such selection prove necessary.

1 Figures released by the Communicable Disease Report of 26 May 2000 (Vol 10, No 21) cite 41,173 cases of HIV infection in the UK—that is, less than 0.07% of the population. UK data from the PHLS AIDS and STD Division, Scottish Centre for Infection and Environmental Health; Institute of Child Health; London and Oxford Haemophilia Centre—on behalf of UK Haemophilia Centre Directors Organisation. HIV infection is currently anticipated to be around 10 times higher, an estimate that would seem to be underscored by the recent study carried out at St Mary’s Hospital (Ward C, Tudor-Williams G, Cottaza T, et al. Prevalence of hepatitis C virus infection in women attending an inner London obstetric department: uptake and acceptability of an antenatal testing. Gut 2000;47:277–80), which reported a prevalence of HCV infection in 0.8% of women who took part, compared with 0.6% of women who were virus negative. In the US, the HCV infection is reported to be possibly four times higher than HIV with 3.5 million affected and 30,000 new cases each year (Turkington C. Hepatitis C: the silent killer. Chicago: Contemporary Books, 1998:xvi).

Screening for genetic haemochromatosis in blood samples with raised alanine aminotransferase

EDITOR,—Bhavani et al (Gut 2000;46:707–10) claim to have identified 12 patients

www.gutjnl.com
haemochromatosis. Since then, the Health Authority has awarded us continuing revenue for this targeted screening, and included in these monies are the clinical, clerical, and nursing costs incurred in providing this service as a routine for patients in our District.

NOTES

American College of Gastroenterology 2001 International GI Training Grants Programme

The ACG International GI Training (IGT) Grant Programme provides funding for clinical or research training in gastroenterology and hepatology so that an individual can acquire or develop new knowledge, skill, or a technical skill. This newly acquired knowledge or skill will then be used to improve patient care in the applicant’s geographic area. Physicians outside of the United States and Canada are eligible to apply. At least one fellowship with a maximum of $10,000 per IGT fellowship will be awarded during 2001, for a training period of not less than six months. Awards will be made by a special committee of the ACG and will be based upon the applicant’s credentials, the merit of the proposed training by the selected applicant, the potential for enhancing the field of gastroenterology in the applicant’s home country. Application forms can be obtained from the ACG administrative office: 49000 South 31st Street, Arlington, Virginia 22206-1656. Tel: +1 703 820 7400; fax: +1 703 931 4520; website: www.acg-gi.org. Deadline for submission of applications is 1 April 2001.

Redefining Priorities in Gastroenterology

This congress will be held on 11–14 April 2001 in Monte Carlo, Italy. It will be chaired by Professor Massimo Crespi (Rome, Italy) and Professor Emmon Quigley (Cork, Ireland). Further information: Maddalena Massaro, Project Leader, AISC-AIM Group, Via A Ristori 38, 00187 Rome, Italy. Tel: +39 06 8096818; fax: +39 06 80968229; email: gastro2001@aisc.it.

3rd European Federation of Autonomic Societies (EFAS)

The third European Federation of Autonomic Societies (EFAS) meeting in conjunction with the annual meeting of the sections “Autonomic nervous system” of the German Neurological Society, “Diabetes and Nervous System” of the German Neurological Society, and “Autonomic Nervous System” at the University of Erlangen-Nuremberg, Germany, will be held in Erlangen, Germany on 26–28 April 2001. Further information: Professor Dr M J Hla, Department of Neurology, University or Erlangen-Nuremberg, Schwabachanlage 6, D-91054 Erlangen, Germany. Tel: +49 0131 8534444; fax: +49 9131 8534328; website: www.neurologie.med.uni-erlangen.de/oeffentliche_Veranstaltungen.htm

Falk Workshop

The workshop entitled Update in Inflammatory Bowel Diseases will be held in Ljubljana, Slovenia, on 5 May 2001. Further information: Prof Dr S Marković, University Medical Center Ljubljana, Division of Internal Medicine, Jalepjeva 2, 1525 Ljubljana, Slovenia. Tel: +386 (1) 231 6925; fax: +386 (1) 433 4190; email: sasa.markovic@kclj.si

EPEGS Endosonography Live in Amsterdam

This European Postgraduate Gastro-Surgical School congress will take place on 31 May and 1 June 2001 in Amsterdam, the Netherlands. Further information: Mrs Helma Stockmann/Mrs Joy Goddekoop, European Postgraduate Gastro-Surgical School, Meibergdreef 9, 1105 AZ Amsterdam, The Netherlands. Tel: +31 20 556 3926; fax: +31 20 556 6569; email: WJ.Stockmann@amc.uva.nl; website: www.epeds.nl.

33rd European Pancreatic Club

The meeting will take place on 13–16 June 2001 in Toulouse, France. A training course will be organised on 13 June on “Genomics and post genomics: developments in biomedical sciences”. Further information: Dr Nicole Vaysse, Inserm U531, CHU Rangueil, 31403 Toulouse, France. Tel: +33 (0)5 61 32 24 02; fax: +33 (0)5 61 32 24 03; email: nicole.vaysse@rangelieu.inserm.fr; website: www.ep-c.org.

Gastroenterology and Endoscopy: XIXth European Workshop

This course, to introduce the experienced gastroenterologist to the growing field of therapeutic endoscopy, will be held on 15–20 June 2001 in Brussels, Belgium. Further information: Mrs Nancy Beauprez, Gastroenterology Department, Erasme Hospital, Route de Lennik 808, B-1070 Brussels. Tel: +32 02 555 49 00; fax: +32 02 555 49 01; email: beauprez@ulb.ac.be
