Monocyte chemoattractant protein 1 (MCP-1) released from *Helicobacter pylori* stimulated gastric epithelial cells induces cyclooxygenase 2 expression and activation in T cells

**Background and aims:** To clarify the interaction between gastric epithelial and mucosal T cells, we examined the role of cytokines released from epithelial cells in response to *Helicobacter pylori* water extract protein (HPWEP) in regulating T cell cyclooxygenase 2 (COX-2) expression and activation.

**Methods:** Media from MKN-28 cells incubated with HPWEP for 48 hours were added to Jurkat T cells and human peripheral T cells. C-C and CXC chemokine concentrations in MKN-28 cell media, and COX-2 expression, interferon-γ (IFN-γ), and interleukin (IL)-4 secretions in T cells were determined by western blot analysis and ELISA methods. Distributions of COX-2 positive T cells and monocyte chemoattractant protein 1 (MCP-1) in tissue specimens with *H pylori* associated gastritis were determined as single or double labelling by immunohistochemistry.

**Results:** MCP-1, IL-7, IL-8, and RANTES were detected in media from MKN-28 cells incubated with HPWEP. Media as a whole, and MCP-1 alone, stimulated COX-2 expression and peripheral T cell proliferation. Anti-MCP-1 antibody inhibited media stimulated COX-2 mRNA expression in Jurkat T cells. Media stimulated IFN-γ but not IL-4 secretion from peripheral T cells, while MCP-1 stimulated IL-4 but not IFN-γ secretion. Both stimulated cytokine release, and peripheral T cell proliferation was partially inhibited by NS-398, a specific COX-2 inhibitor. In mucosa with gastritis, COX-2 was expressed in T cells and MCP-1 was localised mainly in epithelial and mononuclear cells. COX-1 levels and the intensity of COX-2 expression in tissue samples were closely related.

**Conclusions:** Cytokines such as MCP-1, released from gastric epithelial cells in response to HPWEP, seem to modulate T cell immune responses, at least in part via COX-2 expression.

Gastric and colonic epithelial cells are involved in immunological and inflammatory processes, serving not only as a surface for nutrient absorption but also as a defence against ingested pathogens, and express and generate soluble inflammatory mediators. In *Helicobacter pylori* associated gastritis, mucosal concentrations of cytokines such as interleukin (IL)-1β, interferon (IFN)-γ, and IL-8 are significantly elevated compared with those in normal mucosa. In response to *H pylori*, IL-8 secreted from gastric epithelial cells has been shown to induce neutrophil accumulation, leading to local inflammation in the gastric mucosa. However, it has yet to be conclusively clarified how infiltration of mononuclear cells such as lymphocytes and macrophages observed in chronic gastritis is regulated in the gastric mucosa, as has been shown in IL-8 neutrophil regulation.

Prostaglandins (PGs), synthesised and secreted by most human tissues and cell types, play key roles in the regulation of humoral immunity and local cell mediated immunity, modulating cytokine and Ig production as well as T cell proliferation and activation. COX, cylooxygenases (COX) catalyse a two step conversion of arachidonic acid to PGG2, the first reaction required for biosynthesis of various PGs. COX-2 is an inducible enzyme whose induction and expression is dynamically regulated by growth factors, mitogens, tumour growth promoters, and physiological stresses. Persistent activation of COX-2 is associated with oncogenesis as well as with increased invasive potential of tumour cells. Our previous studies have suggested that COX-2 expressed in macrophages and mononuclear cells might play an important role in the mucosal repair mechanism in experimental ulcer bearing animals, and in ulceration caused by *H pylori* in humans. In addition, some reports have shown that COX-2 induced in T cells may regulate T cell cytokine release, thereby modulating immune responses. Studies have also shown that T cell polarisation may be a key factor determining whether gastritis worsens or resolves. In coeliac disease, COX-2 expressed in T cells of the small intestine has been suggested to contribute to healing of the diseased mucosa. However, whether T cells express COX-2 in *H pylori* gastritis mucosa or whether T cell activation and polarisation are related to its COX-2 expression is yet to be determined. In addition, it remains to be seen whether soluble factors released from gastric epithelial cells in response to *H pylori* are involved in COX-2 expression and gastric mucosal T cell activation. In the present study, we therefore investigated the interaction between gastric epithelial cells and T cells by examining the role of cytokines released from gastric epithelial cells in response to *H pylori* water extract protein with regard to T cell COX-2 expression and T cell activation.

**Abbreviations:** MCP-1, monocyte chemoattractant protein 1; COX, cyclooxygenase; IL, interleukin; IFN-γ, interferon γ; PG, prostaglandin; HPWEP, Helicobacter pylori water extract protein; FCS, fetal calf serum; NFκB, nuclear factor κB; MIP, macrophage inflammatory protein; ELISA, enzyme linked immunosorbent assay; RT-PCR, reverse transcription-polymerase chain reaction; TBS, Tris buffered saline; LPS, lipopolysaccharide; Th, T helper.
**MATERIALS AND METHODS**

**Preparation of *H pylori* water extract protein**

A mixture of eight clinical isolates and strain NCTC 11637 were resuspended in distilled water, disrupted in a vortex agitator, and centrifuged. The supernatant was subjected to ion exchange chromatography by a stepwise method (0, 0.2, 0.35, and 0.5 mol/l sodium phosphate fraction). The 0.35 mol/l sodium phosphate fraction, containing a final protein concentration of 0.45 mg/ml, was used as the *H pylori* water extract protein (HPWEP).

**Preparation of media from MKN-28 gastric epithelial cells in response to HPWEP**

Confluent MKN-28 cells were incubated with RPMI 1640 medium supplemented with 10% fetal calf serum (FCS) at 37°C in the presence of HPWEP for 48 hours. Media separated by centrifugation for one minute at 10,000 g were immediately added to T cells and cultured for 24 hours. In some experiments, media were stored at −80°C until cytokine measurements.

**T cell culture and treatment**

Jurkat T cells were grown in complete RPMI 1640 medium supplemented with 10% FCS. Human peripheral T lymphocytes (11 *H pylori* uninfected healthy male volunteers, aged 31–45 years) were separated using paramagnetic beads (Dynabeads; Dynal, Oslo, Norway) coated with anti-CD3 antibody. Immunostaining with anti-CD3 antibody showed that 95% of cells isolated by this method were peripheral T cells, consistent with results previously reported.<ref> Jurkat and peripheral T cells were both stimulated with each of the following: media obtained from MKN-28 cells, PMA (20 ng/ml; Sigma, St Louis, Missouri, USA), immobilised anti-CD3 antibody (0.3 µg/ml; Neo Markers, Fremont, California, USA), recombinant human monocyte chemoattractant protein-1 (MCP-1), IL-7, IL-8, and RANTES (R&D Systems, Minneapolis, Minnesota, USA) for 24 hours. A selective COX-2 inhibitor, 10 µM NS-398 (Taisho Pharmaceutical, Japan), or a selective COX-1 inhibitor, 0.03 µM SC-560 (Pharmacia, New Jersey, USA), were added to peripheral T cell media one hour prior to stimulation. In some experiments, Jurkat T cells were also pretreated for one hour with the proteasome inhibitor MG-132 (Peptide Institute, Osaka, Japan) to prevent nuclear factor κB (NFκB) activation.

**RT-PCR and cytokine measurements**

Total RNA was isolated from MKN-28 cells as per instructions in the Total RNA Isolation kit (Qiagen GmbH, Hilden, Germany). Reverse transcription-polymerase chain reactions (RT-PCR) were performed as previously described<ref> using the primers shown in table 1. Amplification products were visualised by ethidium bromide fluorescence in agarose gels. Concentrations of MCP-1, macrophage inflammatory protein (MIP)-1α, MIP-1β, IL-7, IL-8, RANTES, and IFN-γ in media from MKN-28 cells incubated with HPWEP were quantified using commercially available specific enzyme linked immunosorbent assay (ELISA) plates. Responses of peripheral T cell IL-4 and IFN-γ to the media or anti-CD3 antibody were also determined by ELISA. The plates were used according to instructions provided by the suppliers (MCP-1, MIP-1α, MIP-1β, IL-7, IL-8, RANTES (R&D Systems); IFN-γ and IL-4 (Endogen, Cambridge, Massachusetts, USA)). MCP-1 levels were also examined in supernatants of gastric tissue sample homogenates (10 000 g for 15 minutes at 4°C) from 26 *H pylori* gastritis and 12 *H pylori* uninfected subjects. All subjects provided informed consent before endoscopy.

**Quantitative COX-2 mRNA analysis**

Real time quantitative PCR<ref> was performed to measure COX-2 mRNA expression levels in Jurkat T cells stimulated by media...
from HPWEP exposed MKN-28 cells. In brief, RNA isolated from Jurkat T cells as described above was reverse transcribed and subsequent cDNA amplified in the Model 7700 Sequence detector (PE Applied Biosynthesis, Perkin Elmer, Chiba, Japan) with primers, dual labelled fluorogenic probes, and a Taqman PCR Reagent Kit (Perkin Elmer, Branchburgh, New Jersey, USA). Primers and probes are described in table 1. Known concentrations of serially diluted COX-2 and β-actin cDNA generated by PCR were used as standards for quantification of sample cDNA. Copy numbers of cDNA for COX-2 were standardised to those for β-actin from the same sample.

**COX-1 and COX-2 protein expression and COX activity in T cells**

COX protein partially purified, as previously described, was visualised by western blotting using anti-human COX-1 antibody (diluted 1:25; IBL, Gunma, Japan) or COX-2 antibody (diluted 1:25; IBL). COX enzyme activity was determined using a crude T cell fraction, as described previously. Jurkat T cells incubated with agents for 24 hours were disrupted by sonication in ice cold 100 mM Tris HCl (pH 7.8) containing 1.0 mmol/l phenylmethylsulphonyl fluoride and 1.0 μmol/l pepstatin at 4°C. Sonicates of T cells were centrifuged at 10 000 g for five minutes and the resultant supernatant, containing both microsomal and cytosolic fractions, used as the enzyme source for measurement of COX activity. COX activity was expressed as the production of PGE₂, as measured by ELISA (Assay Designs, Ann Arbor, Michigan, USA) in pmol/min/mg protein. The anti-MCP-1 neutralising antibody (R&D Systems) completely suppressed human recombinant MCP-1 stimulated (150 pg/ml) COX activity in Jurkat T cells at 1:1000 titrations. Therefore, we used the neutralising antibody at that 1:1000 titration to test activity in Jurkat T cells.

**Modified MTT assay**

Human peripheral T cell proliferation prepared from 11 H pylori uninfected volunteers as described above was evaluated using a modified MTT assay, a tool known to be useful for quantifying viable cells. Specifically, the MTT assay is a colorimetric assay system which measures the reduction, by viable cell mitochondria, of tetrazolium components into insoluble formazan products. Briefly, 1x10⁶/ml T cells were cultured in RPMI on a 96 well plate in the presence of MKN-28 cell media, anti-CD3 antibody, or MCP-1 for 24 hours, and then each well incubated with 10 μl MTT for 30 minutes. The reaction was stopped by addition of acidic Triton buffer. Samples were measured on a Bio-Rad plate reader at 595 nm.

**Immunohistochemistry**

Three biopsy specimens obtained from the antrum and body were used for histological assessment. Serial 5 μm sections were stained with haematoxylin-eosin and evaluated using the updated Sydney system. Three slides were prepared, consisting of one antrum and two body tissue specimens, for each patient. When the grade was different between the three slides, the median value was obtained as the representative score. This median value for each patient was used for calculation of mean values.

For COX-2 immunostaining in the gastric mucosa, 3 μm sections were deparaffinized and endogenous peroxidase activity blocked with 5% H₂O₂, in Tris buffered saline (TBS). Non-specific binding was blocked with 5% rabbit serum in TBS and tissues incubated with anti-COX-2 antibody (IBL; dilution 1:100) in TBS containing 1% bovine serum albumin for two hours. We quantified COX-2 expression levels in gastric tissue samples by counting mononuclear cells expressing COX-2 and evaluating the staining intensity for 26 H pylori gastritis and 12 H pylori uninfected subjects. Overall intensity was arbitrarily graded as 0 (negative), 1 (<5% cells with positive staining), 2 (5–30%), 3 (30–60%, with strong staining), and 4 (>60%, with very strong staining). Then, the relationship between COX-2 intensity and MCP-1 levels was examined in 26 H pylori gastritis subjects. For MCP-1 immunostaining in the gastric mucosa, tissue samples were immediately embedded in OCT compound. Serial sections were incubated overnight with polyclonal rabbit anti-human MCP-1 antibody (1:100). After washing, bound antibody was detected using the LSAB 2 kit (Dako, Carpinteria, California, USA) with diaminobenzidine as the chromogen. As negative controls, primary antibodies were replaced with isotype matched immunoglobulin.

Double labelling immunofluorescence methods and confocal laser scanning microscopy were used to evaluate the co-localisation of immunoreactivity for the pair of mouse anti-human COX-2 (IBL; dilution 1:20) and rabbit anti-human CD3 (Dako; dilution 1:20). Sections were incubated overnight at 4°C with a mixture of the two primary antibodies, and then with FITC or Texas red conjugated secondary antibodies (horse antirabbit IgG (Vector Laboratories, Burlingame, California, USA) dilution 1:100 and goat antirabbit IgG (Vector) dilution 1:100, for COX-2 and CD3, respectively) followed by nuclear counterstaining with 4', 6-diamidino-2-phenylindole (DAPI; Sigma Chemical) for 15 minutes.

**Statistical analysis**

Results are expressed as mean (SD). For statistical evaluation of group data, a Students’ t-test for paired data and analysis of variance (ANOVA) for multiple comparisons were followed by Scheffe’s F test. A p value of less than 0.05 was statistically significant.

**RESULTS**

**COX protein expression in peripheral T cells and Jurkat T cells stimulated by MKN-28 cell media**

COX-2 expression (lanes c and f in fig 1) was clearly induced in both T cell types stimulated by media from HPWEP exposed MKN-28 cells (fig 1A). In contrast, COX-2 expression was evident only as a faint band in both T cell types when they were directly stimulated with HPWEP (lanes d and g). No COX-2 expression was detected in unstimulated T cells (lanes e and h). To exclude the possibility that COX-2 expression in peripheral T cells is mainly due to macrophage contamination during peripheral T cell preparations, we stimulated peripheral T cells with lipopolysaccharide (LPS) (150 pg/ml). However, we detected no LPS stimulated COX-2 expression in peripheral T cells (data not shown). COX-1 expression levels did not vary for stimulated and unstimulated T cells (fig 1B).

**COX activity in stimulated Jurkat T cells**

Media from MKN-28 cells incubated with HPWEP induced a significant increase in COX activity in Jurkat T cells (fig 2). Jurkat T cells directly stimulated with HPWEP also showed a small increase in COX activity. These results suggest that in response to HPWEP MKN-28 cells secrete chemokines involved in the increase in COX-2 protein expression and COX activity in Jurkat T cells.

**Stimulated cytokine mRNA expression in MKN-28 cells and protein release into the media**

Next we measured mRNA levels for several cytokines by specific RT-PCR (fig 3A). MCP-1, IL-7, and IL-8 mRNA expression was stimulated by HPWEP while RANTES mRNA levels were not significantly changed by HPWEP stimulation. Furthermore, IFN-γ, MIP-1α, MIP-1β, and IP-10 mRNA were not expressed in MKN-28 cells incubated with or without HPWEP. We also measured MCP-1, IL-7, and IL-8 media levels by specific ELISA (fig 3B). The stimulated media contained significant levels of MCP-1 (133 (6.9) pg/ml), IL-7 (2.8 (1.2)
Comparison of cyclooxygenase (COX) activity in peripheral T cells stimulated by MKN-28 cell media. COX-2 protein expression in T cells stimulated by MKN-28 cell media. COX-2 expression in peripheral T cells incubated with media from *Helicobacter pylori* water extract protein (HPWEP) exposed MKN-28 cells (lane c), HPWEP (lane d), and unstimulated MKN-28 cell media (lane e). Lanes f-h: as in lanes a-e except that Jurkat T cells instead of peripheral T cells are represented. Lanes a and b indicate COX-2 positive control (70 kDa) and COX-1 positive control (68 kDa), respectively. (B) COX-1 protein expression in T cells stimulated by media from MKN-28 cells. Lane a, COX-1 positive control; lane b, COX-2 positive control; lanes c–h, as in (A) except that COX-1 instead of COX-2 expression is represented. Each panel is representative of four separate experiments.

**Figure 1** Cyclooxygenase [COX] protein expression in peripheral T cells and Jurkat T cells stimulated by MKN-28 cell media. (A) COX-2 protein expression in T cells stimulated by MKN-28 cell media. COX-2 expression in peripheral T cells incubated with media from *Helicobacter pylori* water extract protein (HPWEP) exposed MKN-28 cells (lane c), HPWEP (lane d), and unstimulated MKN-28 cell media (lane e). Lanes f-h: as in lanes a-e except that Jurkat T cells instead of peripheral T cells are represented. Lanes a and b indicate COX-2 positive control (70 kDa) and COX-1 positive control (68 kDa), respectively. (B) COX-1 protein expression in T cells stimulated by media from MKN-28 cells. Lane a, COX-1 positive control; lane b, COX-2 positive control; lanes c–h, as in (A) except that COX-1 instead of COX-2 expression is represented. Each panel is representative of four separate experiments.

**Figure 2** Comparison of cyclooxygenase (COX) activity in Jurkat T cells. COX activity in stimulated and unstimulated Jurkat T cells was determined as described in materials and methods. Jurkat T cells were stimulated with *Helicobacter pylori* water extract protein (HPWEP+Jurkat T cells), media from HPWEP exposed MKN-28 cells (HPWEP/MKN-28 medium+Jurkat T cells), and 20 ng/ml PMA (Jurkat T cells+PMA), respectively. Prostaglandin E2 generated in cell media (lane e). Lanes f except that Jurkat T cells instead of peripheral T cells are represented. Lanes a and b indicate COX-2 positive control; lane b, COX-2 positive control; lanes c–h, as in (A) except that COX-1 instead of COX-2 expression is represented. Each panel is representative of four separate experiments. Values are mean (SEM) of four separate experiments. *p<0.05.

**Figure 3** mRNA and protein expression of cytokines in MKN-28 cells and their release into the media. (A) Monocyte chemoattractant protein 1 (MCP-1), interleukin (IL)-7, RANTES, and IL-8 mRNAs were found in *Helicobacter pylori* water extract protein (HPWEP) exposed MKN-28 cells. In contrast, interferon γ (IFN-γ), macrophage inflammatory protein (MIP)-1α, MIP-1β, and IP-10 mRNAs were not expressed. Each panel is representative of four separate experiments. (B) Cytokine levels were determined as described in materials and methods. Each cytokine was determined in duplicate for each sample. Values are mean (SEM) of four separate experiments.

Factors are also involved in COX-2 expression in Jurkat T cells. Pretreatment of Jurkat T cells with MG-132 abrogated both MKN-28 cell media and MCP-1 stimulated COX-2 expression in Jurkat T cells. On the other hand, IL-7 at 5 pg/ml, IL-8 at 40 pg/ml, and RANTES at 600 pg/ml concentrations identified in MKN-28 media, did not stimulate COX-2 expression in Jurkat T cells, as determined by western blot analysis.

**COX-2 mRNA levels and COX activity in Jurkat T cells were inhibited by anti-MCP-1 neutralising antibody** Media from MKN-28 cells incubated with HPWEP induced a significant increase in COX-2/β-actin mRNA levels in Jurkat T cells (fig 4). Jurkat T cells directly stimulated with HPWEP also showed a moderate increase in COX-2/β-actin mRNA. Anti-MCP-1 neutralising antibody (1:1000 titration) significantly suppressed COX-2 mRNA levels in Jurkat T cells stimulated with the MKN-28 media, suggesting that MCP-1 in the media stimulated COX-2 mRNA expression in Jurkat T cells. Then we investigated whether the neutralising antibody could
MCP-1 released from MKN-28 cells is involved in T cell proliferation via COX-2 activation (fig 6A).

**IFN-γ and IL-4 in supernatant from cultured peripheral T cells**

IFN-γ concentrations in supernatants from peripheral T cells significantly increased in response to stimulation by media from HPWEP exposed MKN-28 cells (172 (15.8) pg/mg protein) while IL-4 concentrations (2.0 (0.8) pg/mg protein) did not significantly increase in response to stimulation. IFN-γ concentrations also increased in response to stimulation by anti-CD3 antibody (218.3 (24.8) pg/mg protein) whereas IL-4 failed to respond (1.8 (0.9) pg/mg protein). NS-398 significantly inhibited this media stimulated IFN-γ release (134.2 (11.2) pg/mg protein) whereas SC-560 did not significantly inhibit IFN-γ release (161.8 (14.1) pg/mg protein). There was no increase in basal IFN-γ levels (27.2 (6.2) pg/mg protein) in response to T cell stimulation by MCP-1 at 100 pg/ml (fig 6B) whereas IL-4 concentration (22.5 (1.9) pg/mg protein) significantly increased. NS-398 significantly inhibited this MCP-1 stimulated IL-4 release (14.6 (1.3) pg/mg protein) while SC-560 had no effect on IL-4 release (20.2 (2.5) pg/mg protein) (fig 6C).

**Distribution of COX-2 positive T cells and MCP-1 positive cells in the gastric mucosa**

FITC labelled (green) cells in the lamina propria in fig 7A show COX-2 immunoreactivity. Figure 7B shows mucosal T cells labelled with Texas red conjugated anti-CD3 antibodies for the same section. Double immunostaining for COX-2 and mucosal T cells demonstrated the presence of COX-2 positive mucosal T cells in the lamina propria of *H pylori* infected gastritis mucosa (fig 7C). In contrast, there were no COX-2 positive T cells in *H pylori* uninfected gastritis mucosa, and just a few CD3 positive cells (fig 7D). In fig 7E, we can see MCP-1 immunoreactivity in surface epithelial cells, as well as in a number of mononuclear cells.

**Correlation between MCP-1 levels and intensity of COX-2 expressions in gastric mucosal samples**

MCP-1 levels were significantly greater in *H pylori* infected tissue samples (166.1 (32.6) pg/mg protein) than in uninfected mucosal samples (81.6 (7.7) pg/mg protein). There was a significant correlation (r=0.869, p<0.0001) between intensity of mononuclear cell infiltration and MCP-1 levels in gastric mucosal samples from patients with and without *H pylori* infection.
stimulation by anti-HPWEP. Peripheral T cells were described in materials and methods. Peripheral T cells were stimulated as described in materials and methods. Peripheral T cells were stimulated as described in materials and methods. Peripheral T cells were stimulated as described in materials and methods.

DISCUSSION

In this study, we investigated the role of *H pylori* induced cytokine release from gastric epithelial cells in T cell COX-2 expression and activation, in vitro and in vivo. Several lines of evidence in the present study suggest that MKN-28 cells, in response to HPWEP stimulation, secreted various cytokines, including MCP-1, and thus induced T cell COX-2 expression and activity. Firstly, media from HPWEP exposed MKN-28 cells stimulated COX-2 mRNA and protein expression in T cells. Secondly, RT-PCR and specific ELISA showed that in MKN-28 cells, MCP-1 mRNA was expressed and MCP-1 protein released in response to HPWEP. Thirdly, in Jurkat T cells, MCP-1 stimulated COX-2 expression levels and COX activity while anti-MCP-1 neutralising antibody suppressed both COX-2 mRNA expression and COX activity stimulated by MKN-28 cell media. Therefore, MCP-1 seems to play a role in COX-2 expression in T cells. Although other studies to date have shown that IL-8, a CXC chemokine released from gastric epithelial cells, may be involved in mucosal neutrophil infiltration, few have considered the role of MCP-1 expression, a C-C chemokine, in gastric epithelial cells. As far as we know, this is the first report to show a relationship between MCP-1 release from gastric epithelial cells and induction of COX-2 expression leading to T cell activation. However, COX activity in media stimulated Jurkat T cells was not completely suppressed by anti-MCP-1 neutralising antibody. This suggests that other cytokines in the MKN-28 cell media are also involved in COX-2 protein expression and COX activity in T cells. Recently, CXC chemokines as well as C-C chemokines have been shown to act as chemoattractants for T cells and to induce cytokine production from T cells. However, in the present study, we were not able to detect any MIP-1α or MIP-1β in the stimulated media. Furthermore, IL-7, IL-8, or RANTES did not stimulate Jurkat T cell COX-2 protein expression. Thus it appears that in addition to MCP-1, other factors may be involved in T cell COX-2 expression. As media MKN-28-cell conditioned media that contain MCP-1 could not stimulate COX-2 protein expression in Jurkat T cells pretreated with MG-132, it appears that MCP-1 may stimulate COX-2 expression via NFκB activation.

We also found that COX-2 induction, as seen with media from MKN-28 cells and MCP-1, might play an important role in peripheral T cell cytokine production and proliferation. NS-398, a specific COX-2 inhibitor, induced a moderate reduction in peripheral T cell proliferation, whether stimulated by media or MCP-1 alone.

In parallel with media induced peripheral T cell proliferation, IFN-γ release was also released from peripheral T cells in response to the media. This IFN-γ release was again partially inhibited by NS-398, suggesting that COX-2 is also involved in producing IFN-γ, a major cytokine linked to functional T cell polarisation toward a T helper 1 (Th1) profile. Thus media from HPWEP exposed MKN-28 cells appear to shift T cells in a Th1 direction. These data are consistent with a recent report suggesting that *H pylori* induced mucosal inflammation is mediated by Th1 predominance. On the other hand, MCP-1, which also stimulated COX-2 expression and COX-2 dependent T cell proliferation, was found in the present study to stimulate IL-4 secretion from peripheral T cells while having no effect on IFN-γ secretion. This suggests that MCP-1 alone is linked to Th2 polarisation. The results of the present study are also consistent with previous studies linking MCP-1 to Th2 polarisation. Although we do not know why media containing

Figure 6  T cell cytokine production and proliferation. (A) Proliferation of activated peripheral T cells was determined as described in materials and methods. Peripheral T cells were stimulated by anti-CD3 Ab (0.3 µg/ml), Helicobacter pylori water extract protein (HPWEP), MKN-28 medium, HPWEP/MKN-28 medium in the presence of 10 µM NS-398, HPWEP/MKN-28 medium in the presence of 10 µM NS-398, HPWEP/MKN-28 medium in the presence of 100 µM NS-398, HPWEP/MKN-28 medium in the presence of 100 µM NS-398. For each MTT assay, samples were determined in triplicate. *p<0.05. (B) Interferon γ (IFN-γ) production was determined as described in materials and methods. Interleukin 4 (IL-4) production was determined as described in materials and methods. Each value represents the mean (SEM) of 11 separate experiments.
MCP-1 failed to stimulate IL-4 secretion from peripheral T cells, other factors in the media might be involved in IFN-γ secretion and IL-4 inhibition in these cells. Alternatively, it is possible that IFN-γ downregulates CD30, a marker of IL-4 response.\textsuperscript{13} In the present study, we also found that COX-2 expression in T cells was apparently linked to both Th1 and Th2 polarisation. NS-398 partially inhibited IFN-γ release stimulated by media from HPWEP exposed MKN-28 cells. In addition, NS-398 also induced a moderate reduction in MCP-1 expression in gastric epithelial cells and mononuclear cells in the lamina propria, as seen in H pylori infected gastritis.

Previous studies have reported that MCP-1 is localised in epithelial cells of the colon and that its expression correlates with T cell infiltration in inflammatory bowel disease mucosa.\textsuperscript{14,15} A previous study using PCR analysis indicated possible MCP-1 expression in a gastric epithelial cell line.\textsuperscript{16} We demonstrated in the present study that MCP-1 is in fact released from gastric epithelial cell lines in response to HPWEP. In addition, we found for the first time that MCP-1 was localised mainly in gastric epithelial cells and also partly in mesenchymal cells of H pylori infected mucosa. MCP-1 immunoreactivity was limited to surface epithelial cells, with no MCP-1 immunoreactivity seen in either glandular cells or H pylori uninfected epithelial cells. This suggests that H pylori in proximity to pit cell surfaces might affect MCP-1 expression in the gastritis mucosa.

MCP-1 levels in these gastritis tissue samples were closely related to intensity of COX-2 expression, consistent with our in vitro findings that MCP-1 stimulated increases in COX-2 expression levels in T cells. This leads us to hypothesise that MCP-1 released from gastric epithelial cells triggers COX-2 induction and T cell infiltration in H pylori infected gastric mucosa. However, it is not yet known whether MCP-1 released from gastric epithelial cells is actually involved in Th2 polarisation in gastritis mucosa in vivo.
