If you have a burning desire to respond to a paper published in the Gut, why not make use of our “rapid response” option? Log on to our website (www.gutjnl.com), find the paper that interests you, and send your response via email by clicking on the “letters” option in the box at the top right hand corner. Providing it isn’t libellous or obscene, it will be posted within seven days. You can retrieve it by clicking on “read letters” on our homepage.

The editors will decide as before whether to also publish it in a future paper issue.

LETTERS

Investigation of chronic diarrhoea

I congratulate the authors of the recently revised “BSG guidelines for the investigation of diarrhoea” for their excellent overview of this important clinical problem. (Gut 2003; 52[suppl V]:v1–15) I would however take issue with the suggestion that measurement of stool volumes in outpatients is impractical. In my experience such measurement is readily achievable and cheap, merely requiring a suitable container and some weighing scales. A three day stool collection should be considered early in the investigation of chronic diarrhoea, particularly if a factitious aetiology is suspected which is unfortunately often underdiagnosed and overinvestigated.1

Interstitial pneumonia associated with autoimmune pancreatitis

We read with interest the article by Kamisawa et al reporting IgG4 positive plasma cells in peripancreatic tissue, extrahepatic bile duct, gall bladder, and salivary gland (Gut 2003;52:683–7). The association of retroperitoneal fibrosis and sclerosing pancreatitis with IgG4 bearing plasma cells in the tissues of both lesions has been also reported.1

We would like to report the first case of interstitial pneumonia associated with autoimmune pancreatitis and IgG4 positive plasma cells in the interstitium.

Hyperamylasemia was detected in a routine blood examination in a 63 year old man who had been treated for duodenal ulcer at a clinic. He was admitted to our hospital for further examination. He did not complain of epigastralgia or back pain. Serum amylase was 323 (139–130 IU/l), IgG was elevated to 2150 (800–1600 mg/dl), and IgG4 was 1690 (<80 mg/dl). Antinuclear antibody, anti-SS-A antibody, anti-SS-B antibody, rheumatoid factor, and antiphilomast muscle antibody were all negative. Abdominal ultrasonography and computed tomography (CT) showed swelling of the head and tail of the pancreas. Endoscopic retrograde pancreatography showed irregular narrowing of the main pancreatic duct in the head and tail. Magnetic resonance cholangiography showed estrinsic stenosis of the lower common bile duct. The patient was diagnosed with autoimmune pancreatitis but he refused steroid therapy and was followed as an outpatient.

Three months later, homboucyming of the bilateral lower lung field was detected in a follow up abdominal CT. Chest CT revealed ground glass attenuation in the middle and lower lobe, and honeycombing predominantly at the back of the lower lobe, bilaterally (fig 1A). (Figure 1 A–D is available for viewing online at http://gut.bmjournals.com/cgi/letters/52/5/683/#127.) Retrospectively, a slight reticulon shadow in the lower lung field was detected in the chest roentenogram taken at the first admission but the lesion had progressed over three months. He was readmitted for further examination. He had a history of smoking 30–40 cigarettes a day for approximately 40 years. IgG was 3934 mg/dl, IgG4 was 2690 mg/dl, KL-6 was 1440 (<500 u/ml), serum amylase was 142, and lipase was 121 (0–49 IU/l). Schirmer’s test indicated a decrease in lacrimal secretion. Swelling of the head and tail of the pancreas were not changed on abdominal ultrasonography and CT.

With gallium scintigraphy, uptake was observed bilaterally at the back of the lower lobe, suggesting active pneumonia. Histology obtained by transbronchial lung biopsy from segment 8a of the right lobe showed marked thickening of the alveolar septum with marked infiltration of plasma cells and lymphocytes (fig 1B). Immunostaining with IgG4 was performed using the immunoperoxidase method (mouse anti-human IgG4; ICN Biomedicals, Inc, Ohio, Canada). Infiltration of IgG4 positive plasma cells was pancretic in the alveolar septum (fig 1C).

Macrophages in the alveoli are considered to be due to smoking which often coexists with interstitial pneumonia in smokers.2 Because interstitial pneumonia associated with autoimmune pancreatitis was strongly suggested, prednisolone (40 mg/day) was administered for two weeks and then the dose was tapered. Chest CT taken two weeks after treatment showed that the ground glass attenuation in the middle and lower lobe had disappeared whereas the honeycombing remained (fig 1D).

Abdominal ultrasonography performed two weeks after treatment showed a marked decrease in the swelling the pancreas. In the present case, infiltration of IgG4 positive plasma cells in the interstitium strongly suggests that the interstitial lung disease was associated with autoimmune pancreatitis. Interstitial pneumonia associated with Sjogren’s syndrome is unlikely in this case although there was decreased larcral secretion. Sicca syndrome observed in autoimmune pancreatitis is distincetly from classical Sjogren’s syndrome in that it is negative for anti-SS-A or anti-SS-B antibodies, serum IgG4 is elevated, and infiltration of IgG4 positive plasma cells in the salivary glands is observed.3

We would like to report the first case of interstitial pneumonia associated with autoimmune pancreatitis, in some cases, may be part of a systemic disease associated with IgG4.

Author’s reply

We thank Dr Taniguchi et al for the interesting presentation of interstitial pneumonia associated with autoimmune pancreatitis (AIP).

We have experienced 24 cases of AIP but no cases showed interstitialial pneumonia previously. Recently, we chemically examined the organs of eight patients with AIP using anti-IgG4 antibody. IgG4 positive plasmacytic infiltration was identified in the portal area of the liver, gastric mucosa, colonic mucosa, and bone marrow as well as in the pancreas, peripancreatic tissue, extrahepatic bile duct, gall bladder, salivary gland,
and lymph nodes of patients with AIP. However, few IgG4 positive plasma cells were observed in identical control specimens. From these findings, we proposed a new clinicopathological entity of IgG4 related autoimmune disease, and stressed that AIP is not simply pancreatitis but a pancreatic lesion involved in this systemic autoimmune disease. As IgG4 positive plasmacytic infiltration was observed in the transbronchially biopsied pulmonary specimens of the patient with AIP (unpublished data), it is likely that interstitial pneumonia occurs in association with AIP.

The diagnostic dilemmas in discrimination between pancreatic carcinoma and chronic pancreatitis

In response to the letter of Harlozinska-Pawlak et al. (Gut 2003;52:1526–9) commenting on our study, we agree with the remarks made in relation to the difficulties in discriminating between chronic pancreatitis and adenocarcinoma using currently employed diagnostic imaging and tumour marker analysis. Our study was aimed at determining the risk of cancer development in patients with proven chronic pancreatitis, examining age and sex standardised incidence ratios calculated from the number of observed cases of pancreatic cancer in our cohort of 373 patients with predominantly alcohol related chronic pancreatitis to the number of cases expected in the National Cancer Registry. Our study design did not take into consideration diagnostic dilemmas and focused purely on cancer risk in our cohort of patients using defined stringent criteria. Indeed, we previously underlined the interest of biological markers to this situation (for example, CA19-9 and circulating K-ras) 1,2 however these markers have problems with both sensitivity and specificity.

We acknowledge that given the difficulties in diagnosing cancer in this situation, the establishment of new tumour markers such as tissue polypeptide specific antigen (TPS) with proven good sensitivity and specificity should provide for progress in the future. It has to be stressed however that TPS, a marker of proliferation activity, is not specific to pancreatic cancer, and other digestive and non-digestive cancers as well as benign chronic disorders may have high levels of this marker. We validated data concerning tumour markers, either alone or in combination, in distinguishing pancreatic cancer from chronic pancreatitis should prove important in diagnostic situations.

In search of the correct strategy for preventing the spread of HCV infection

Hepatitis C virus (HCV) infection is an emerging global healthcare issue. Apart from affecting approximately 3% of the world population, HCV is also a silent disease—the majority of incidences go unrecognised and are unknowingly as sources of infection to others. 1,2 Add to that the scant information defining the transmission routes and rates of HCV, the programme presented by Skipper et al in their paper measuring the diagnosis and prevention of HCV in a prison outreach clinic (Gut 2003;52:1500–4) seems a model that could significantly constrain a situation that appears to be reaching epidemic proportions, especially here in Southern Italy.

Studies on the epidemiology of HCV infection in Italy have shown that this infection represents a major health problem throughout Southern Italy, with a prevalence of up to 12.6% in the general population. 3–5 Also, HCV has been linked to the high incidence and mortality rates for liver cancer found in our region (standardised incidence rates per 100 000 inhabitants: 18.9 male, 13.2 female; mortality rates 15.2 male, 9.0 female). 6–8 Between January 2000 and December 2001, we performed a cross sectional study of 5844 individuals (4260 men; 1584 women) from the general population and from five select groups in the Metropolitan area of Naples, with the purpose of assessing the prevalence of HCV infection in select groups with different exposure patterns in Southern Italy. Below are the preliminary data from this study:

- general population (n = 1972; prevalence 8.5%);
- imprisonment (n = 524; prevalence 37.4%);
- intravenous drug use (n = 1436; prevalence 31.8%);
- haemodialysis (n = 678; prevalence 2.9%);
- routine medical examination of patients (n = 453; prevalence 12.6%);
- health care workers at the National Cancer Institute of Naples (n = 781; prevalence 6.4%).

Our findings confirm the high prevalence among drugs users (31.8%) but the highest prevalence was found among male prisoners (37.4%), particularly those in the 30–49 year age range (47.3%). In fact, we concur with Skipper et al that “those involved with IDU frequently pass through the penal system and spend time in prisons” thus indicating a probable interrelationship between these two groups.

Our other findings from this study shed light on the unusually high prevalence of this disease in the general population of Southern Italy. Previous reports have shown that the prevalence of HCV infection is generally low in the general population of most industrialised countries (<5%). In Southern Italy, the high prevalence of HCV infection may be the result of past iatrogenic transmission, aggravated by:

1. extensive use of glass syringes or non-sterile syringes; and
2. social conditions which may indirectly favour the spread of infection:

- general poverty,
- poor education etc., 9,10 and
- especially among females, haemodialysis procedures.

Prisons do play a significant role in the hepatitis C epidemic, especially as the same social conditions mentioned above which may facilitate spread of infection also predict imprisonment. 11 In fact, a disproportionate share of the burden of HCV infection is found among those who pass through correctional facilities. 12 As stated previously, HCV seroprevalence is high among this group. A history of incarceration is one of the strongest associations with HCV seropositivity. 13 Yet despite these high levels, reports of HCV transmission in the prison setting are uncommon. 14 In fact, studies have revealed that an overwhelming number of new infections are being brought into prisons via inmates who are already previously infected; drug users are most likely to become infected with HCV at the beginning of their addiction—long before being imprisoned for the first time. 14 Yet it must be taken into account the fact that the dynamic movement of people in and out of prisons makes it very difficult to detect transmission. 15 While the available data do not prove that infections are acquired in prison, they do indicate prisons as high risk transmission for the spread of HCV. 16

What is of great concern to us are the implications of the previous and following data:

- HCV is easily transmitted parenterally.

References

Our prisons are overcrowded (the Secondigliano prison located in Naples, for example, has 1350 prisoners and only 790 beds). In Southern Italy, the health system in general is less efficient and less meticulous than that in the north of Italy (and in the rest of the EU and in the USA).

We have no harm reduction programmes in place.

The limited availability of prevention methods has been linked to the transmission of HCV infection. This association, and its relation to inadequate management of a man-made problem, surely opens up our National Health System to costly retributions. If it can be proven that an inmate contracted HCV while incarcerated, due to a lack of sufficient care and prevention on the part of the system, he then has the right to seek judicial indemnification—a costly process for all concerned.

How much more economical to initiate admission screening programmes in our overcrowded prisons where, as detailed above, there is an identifiable elevated risk. By so doing, we move one step closer to correcting a problem that is grossly out of control. As HCV is associated with different kinds of neoplasms (liver, possibly non-Hodgkins lymphoma) and with autoimmune diseases (crigobilinemia, thyroiditis, Hashimoto thyroiditis), which develop after the virus has caused immune system alterations, a routine health screening on admission to prison presents a unique opportunity to identify health needs and plan health services at an early stage. In fact, studies have found that screening provides a preventive function to those who had previously presented for a hepatitis C test, regardless of the result, were less likely to have recently engaged in high risk behaviour (that is, sharing injecting equipment).

How much more economical to initiate a good educational harm reduction programme such as that implemented by Skipper et al. Correctional interventions of this kind stand to benefit not only the inmates themselves and their families and partners, but also the public health of the communities to which the vast majority of inmates return. By implementing such a programme, the healthcare system would be doing its job, demonstrating effective management of a social problem and sustaining the welfare of its people.

Cross reactivity due to positive canrenone interference

Canrenone is a selective competitive inhibitor of the aldosterone receptor and a diuretic drug commonly used in the treatment of cirrhotic patients both with and without ascites. The aim of our observation was to determine if canrenone cross reacts with aldosterone in an immunoradiosorbent assay kit used for the determination of aldosterone concentration, according to the Child-Pugh classification for liver cirrhosis. Canrenone, for in vitro experiments, was a gift from GliEnne Pharma (Group Therabel). Diabetic nephropathy. Canrenone, potassium canrenoate, and spironolactone are often used with digoxin in clinical practice and can cause false low results in common assays for digoxin (that is, Asym MEIA-Abbott) due to negative cross-reactivity, and falsely elevated serum digoxin concentrations with the fluorescence polarization immunoassay for digoxin.

Human hepatic stellate cells, isolated from wedge sections of normal human liver unsuitable for transplantation, were separated, after digestion with collagenase/proteinase from other liver non-parenchymal cells by ultracentrifugation over gradients of stachar. Cells were cultured on plastic culture dishes in Iscove’s modified Dulbecco’s medium, supplemented as described elsewhere. Cells were isolated (1x10^6 cells in well dishes) and incubated with increasing concentrations of canrenoate or with no drug (SFIF or control conditions), after a 24 hour incubation period in serum free insulin free (SFIF) medium. After 24 hours, medium was removed and cells were then resuspended in a total volume of 1 ml and aliquots of 200 μl were processed for aldosterone assay (Radim kit, Italy; KS17CT, RIA method). The result was expressed as percentage linearity (0.007 (0.003); 0.018 (0.004); 0.027 (0.003) nmol/l (mean (SD)); n = 3). As values obtained in SFIF samples were below the lower limit of the assay (0.009 (0.001)), it is conceivable that these cells do not produce aldosterone under basal conditions. To further validate this observation, we then spiked sera with increasing concentrations of canrenoate (10, 50, 100 μM) and subsequently, aldosterone concentrations were determined. Sera were collected from patients with different degrees of liver disease (from acute hepatitis (n = 1), to non-alcoholic steatohepatitis (n = 1), or chronic active hepatitis with (n = 3) or without (n = 6) cirrhosis). Aldosterone concentrations were as follows: 0.32 (0.18), 0.63 (0.22), 0.85 (0.26), and 1.07 (0.35) nmol/l (mean (SD); n = 11). Comparing these concentrations with the increasing concentrations of canrenoate spiked into sera, no significant cross-reactance was found (from r = 0.874 to r = 0.988; p<0.001). To date, only positive interferences leading to falsely high digoxin readings, including those due to spironolactone and canrenone, have been reported. Negative interference is much more dangerous. Toxic concentrations may remain undetected. Less severe negative interferences or interferences from clinically less significant cross reagents have been reported. Assay manufacturers should assess potential cross reactivity in the presence of the primary ligand. This difficulty may apply to immunoassays and cross reagents other than digoxin and canrenone. Pathologists and clinicians should be aware of negative interference so that intoxication due to drug dosing guided by monitoring of its concentration in serum can be avoided. For positive interference of a low cross reaction substance, such as in our observation, false positive test results for hormonal and electrolyte disturbances during liver cirrhosis can be avoided.
reactivity could hardly affect biological determinations.

Responses to endothelin-1 in patients with advanced cirrhosis before and after liver transplantation

In response to Helmy’s comments in his recent letter (Gut 2004;53:470–1), we wish to emphasize the following points, many of which were clearly stated in our original paper.

In agreement with the comments on “generalised vasodilatation” in cirrhosis, we made it clear that basal forearm blood flow was normal in our patient cohort despite the presence of a vasodilated circulation, as evidenced by a reduced systemic vascular resistance index. As pointed out in our paper, this observation is consistent with findings of previous studies and suggests that beds other than the forearm circulation, such as those of the splanchic and pulmonary circulation, were dilated in our patients.

With regard to the issues raised about the use of one arm plethysmography, our own results and those of others have shown that under well controlled circumstances the effects of external stimuli on results obtained using this approach are minimal. Indeed, in our study, the results of forearm plethysmography were very consistent across both the control and cirrhotic patient groups.

However, it is important to acknowledge that simple forearm plethysmography could be affected by changes in systemic haemodynamics (due for example to the effects of drug infusions). However, as stated in the text, neither heart rate nor blood pressure altered significantly throughout the course of the experiment.

In forearm resistance arteries (and elsewhere), ET_{A} receptors on vascular smooth muscle and endothelial cells mediate opposing effects on vascular tone. Thus, ET_{A} blockade could result in either vasodilatation or vasoconstriction, depending on which receptor subpopulation is most affected.

In our hands, preliminary experiments with the ET_{A} blocker BQ123 (an ET_{A} antagonist), we wish to re-emphasise these were two very different experiments in two separate groups of patients, asking two different questions. We observed:

(1) that ET-1 infusion in these advanced cirrhotic patients produced vasoconstriction (one and BQ123 (an ET_{A} antagonist), we wish to describe three groups which they labelled “distressed high utilizers,” “distressed low utilisers,” and “tolerant low utilisers.” The authors defend their analysis on clinical grounds and point to treatment implications for each of these groups.

We feel that there are some fundamental points about the nature of cluster analysis that readers of this paper should not overlook. Cluster analysis was initially developed to confirm that IBS and functional dyspepsia exist as separate clinical entities, and to evaluate specific symptom subgroups, as described by the current Rome criteria.

The term “cluster analysis” describes a range of procedures which use empirical methods to form groups of highly similar entities. While the notion that cluster analysis is solution seeking, open research techniques is essentially solution imposing: that is, clustering methods will always place objects into groups. Furthermore, as there are no formal statistical procedures to evaluate the resulting solution, the reasonableness of any solution is determined only on the basis of personal judgement. This is a problem. Indeed, critics of the approach have argued that cluster analysis encourages “naive empiricism”—that is, inclusion of as many variables as possible in the hope that a meaningful structure will come out. However, proponents of cluster analysis have suggested that careful selection of variables on theoretical grounds can overcome this problem.

It is intuitively obvious that any single entity can be classified according to a broad range of dimensions, and Guthrie et al have certainly demonstrated this with respect to IBS. However, we rarely classify any object or entity according to all possible dimensions simultaneously; this would lead to a complex set of descriptors which may be unwieldy and contain many redundancies. Rather, we tend to select a subset of dimensions that best suit our purposes in forming a classification.

There are certainly theoretical grounds for considering psychological involvement when evaluating patients with IBS. Its association with psychological disturbance and health care seeking has been well described, and our understanding of these factors has contributed greatly to current therapeutic approaches. However, we challenge the proposed classification of IBS according to psychological involvement on two grounds. Firstly, we view this as a step towards naive empiricism; other researchers may be encouraged to replicate the analyses across a broader and even more diverse (yet irrelevant) range of dimensions. This is not likely to produce a parsimonious classification scheme that is useful in either clinical practice or the research setting. Secondly, classification of IBS according to psychological and/or psychiatric involvement

Cluster’s last stand

Guthrie and colleagues (Gut 2003;52:1616–22) described the results of cluster analysis in a patient group with severe intolerable nausea (IBS). Their analysis investigated a broad range of factors in addition to these included psychosocial measures (psychiatric involvement, health service encounters, quality of life) and physiological parameters (rectal thresholds). The authors have demonstrated that severe IBS can be classified according to more difficult characteristics and, in particular, according to the level of psychological distress, service encounters, and rectal sensitivity. They describe three groups which they labelled “distressed high utilisers,” “distressed low utilisers,” and “tolerant low utilisers.” The authors defend their analysis on clinical grounds and point to treatment implications for each of these groups.

We feel that there are some fundamental points about the nature of cluster analysis that readers of this paper should not over-
may stigmatis some patients with this complaint; one of the unfortunate consequences of classification is the tendency to attach labels to the subgroups that emerge.

Small bowel carcinoma and coeliac disease

We thank Howdle et al for their comments on our study, detailed recently in their letter (Gut 2003;53:470). In their British Society of Gastroenterology (BSG) National Survey,1 Howdle et al relied mainly on gastroenterologists and surgeons to report cases of small bowel carcinoma and whether they were associated with either coeliac or Crohn’s disease. This may have resulted in underestimation of associated coeliac disease. In our series, we had two cases in which the original pathologist had failed to recognise the histological features of coeliac disease in mucosa adjacent to the adenocarcinoma.2 The diagnosis of coeliac disease was made after review of the original resections. This problem has been recognised previously3 and results in the underdiagnosis of coeliac disease and further diagnostic delay for the patient with coeliac disease.

While the individual risk for patients with coeliac disease in developing adenocarcinoma of the small intestine is not great, poor survival should prompt rapid evaluation when symptoms occur. In addition, there should be a consideration of whether there is a subset of patients with coeliac disease who would benefit from screening for these cancers. Because patients with coeliac disease do not have a significantly increased risk of duodenal adenomas,4 the role of video capsule endoscopy of the entire small intestine needs to be explored.

Due to an administrative error, one article has been published on two occasions. The journal would like to retract the paper by Lindsay et al in the July issue (Gut 2003;52:981–7) as it is a replicated version of a paper by the same authors in the March issue (Gut 2003;52:363–9). The journal apologises for this error.

NOTICES

British Society of Gastroenterology
Paul Brown Travel Fellowships
The Paul Brown Travel Fellowships are awarded by the Endoscopy Committee of the BSG. They are intended to assist trainee gastroenterologists and established consultants in visits to units outside the United Kingdom for specialist experience and training in endoscopy.

Specialist registrars who have not achieved their CCTS are expected to have the approval of their Postgraduate Dean and their Regional Training Committee for a Travel Fellowship. Applicants are expected to provide confirmation that they have been accepted for training in the unit that they wish to visit.

Successful applicants will be expected to provide a brief written report to the Endoscopy Committee of the outcome of their visit.

Application forms are available from the British Society of Gastroenterology Office, 3 St Andrew’s Place, London NW1 4LB. Email: bsg@mailbox.ulc.ac.uk
