GASTRIC MOTILITY

Gastric motor effects of peptide and non-peptide ghrelin agonists in mice in vivo and in vitro

T Kitazawa, B De Smet, K Verbeke, I Depoortere, T L Peeters

Background and aims: The gastroprokinetic activities of ghrelin, the natural ligand of the growth hormone secretagogue receptor (GHS-R), prompted us to compare the effect of ghrelin with that of synthetic peptide (growth hormone releasing peptide 6 (GHRP-6)) and non-peptide (capromorelin) GHS-R agonists both in vivo and in vitro.

Methods: In vivo, the dose dependent effects (1–150 nmol/kg) of ghrelin, GHRP-6, and capromorelin on gastric emptying were measured by the 14C octanoic breath test which was adapted for use in mice. The effect of atropine, N\(^{\text{A}}\)-nitro-l-arginine methyl ester hydrochloride (l-NAME), or D-Lys\(^{3}\)-GHRP-6 (GHS-R antagonist) on the gastroprokinetic effect of capromorelin was also investigated. In vitro, the effect of the GHS-R agonists (1 \(\mu\)M) on electrical field stimulation (EFS) induced responses was studied in fundic strips in the absence and presence of l-NAME.

Results: Ghrelin, GHRP-6, and capromorelin accelerated gastric emptying in an equipotent manner, with bell-shaped dose-response relationships. In the presence of atropine or l-NAME, which delayed gastric emptying, capromorelin failed to accelerate gastric emptying. D-Lys\(^{3}\)-GHRP-6 also delayed gastric emptying but did not effectively block the action of the GHS-R agonists, but this may be related to interactions with other receptors. EFS of fundic strips caused frequency dependent relaxations that were not modified by the GHS-R agonists. l-NAME turned EFS induced relaxations into cholinergic contractions that were enhanced by ghrelin, GHRP-6, and capromorelin.

Conclusion: The 14C octanoic breath test is a valuable technique to evaluate drug induced effects on gastric emptying in mice. Peptide and non-peptide GHS-R agonists accelerate gastric emptying of solids in an equipotent manner through activation of GHS receptors, possibly located on local cholinergic enterochromaffin nerves.

class of synthetic molecules, termed growth hormone secretagogues (GHS), are known to stimulate growth hormone (GH) release through interaction with a specific receptor, the growth hormone secretagogue receptor (GHS-R). GHS-R was cloned and identified in 1996\(^{1}\) as a novel G protein coupled receptor, almost 20 years after the development of the first GHS.\(^{2}\) Cloning of this receptor allowed the discovery of the endogenous ligand of GHS-R, ghrelin, which was isolated from an unexpected source: the rat stomach.\(^{3}\) Two major forms of the 28 amino acid peptide ghrelin are found in the stomach and plasma: acylated ghrelin, which has an n-octanoylated serine in position 3; and des-acyl ghrelin, which accounts for 80% of circulating ghrelin.\(^{4}\) The n-octanoyl modification appears to be necessary for the growth hormone (GH) stimulatory effect of ghrelin.\(^{5}\)

In addition to its effect on GH secretion, ghrelin is now considered to be an important regulator of energy homeostasis, stimulating food intake and decreasing fat utilisation during periods of negative energy balance.\(^{6–9}\) Moreover, ghrelin may be involved in the regulation of endocrine and exocrine pancreatic function, cardiac function, anxiety, and gastric functions (for a review see Murray and colleagues\(^{7}\)). The various functional roles of ghrelin are supported by the evidence that GHS-R ligand binding sites and mRNA for GHS-R are widely expressed in the central nervous system and in several peripheral tissues.\(^{8–10}\)

There is mounting evidence to support a physiological role for ghrelin in the regulation of gastrointestinal motility. In conscious rats and mice, ghrelin accelerates gastric emptying, enhances small bowel transit, and is able to overcome postoperative ileus.\(^{10–12}\) Exogenous administration of ghrelin also accelerates gastric emptying in humans.\(^{13}\) Recent observations have shown stimulation of interdigestive motility by ghrelin in rats and humans.\(^{14, 15}\)

However, the data obtained in small animals rely on a limited number of observations, mostly because of the lack of a convenient and reliable technique to measure gastric emptying. We decided to adopt the octanoic acid breath test, developed by our group in humans,\(^{16–18}\) for use in mice to evaluate the prokinetic potential of ghrelin. During the past 25 years, several peptide GHS (for example, growth hormone releasing peptide 6 (GHRP-6)) and non-peptide GHS (for example, MK-0677\(^{19}\) and capromorelin\(^{19}\)), have been developed that were orally active and had improved potency and bioavailability to stimulate release of GH. We therefore compared the effects of ghrelin with those of the GHS GHRP-6 (peptide) and capromorelin (non-peptide). Recent studies suggest that ghrelin may activate the enteric nervous system. Therefore, we also investigated the effect of these GHS-R agonists in vitro.

MATERIALS AND METHODS

Chemicals

Rat ghrelin was obtained from Tocris Cookson (Bristol, UK). GHRP-6 and D-Lys\(^{3}\)-GHRP-6 were purchased from Bachem (Bubendorf, Switzerland). Atropine sulphate and N\(^{\text{A}}\)-nitro-l-arginine methyl ester hydrochloride (l-NAME) were obtained from Sigma (St Louis, Missouri, USA). Capromorelin was a gift from B Coulie (Johnson and Johnson, Cambridge, Massachusetts, USA). L-NAME was obtained from Sigma (St Louis, Missouri, USA). D-Lys\(^{3}\)-GHRP-6 was synthesized as described previously.\(^{20}\)

Abbreviations: GH, growth hormone; GHS, growth hormone secretagogue; GHS-R, growth hormone secretagogue receptor; GHRP-6, growth hormone releasing peptide 6; l-NAME, N\(^{\text{A}}\)-nitro-l-arginine methyl ester hydrochloride; EFS, electrical field stimulation.
Gastroprokinetic effects of ghrelin agonists in mice

Healthy male NMRI mice (30–40 g body weight) were housed in cages at 20–22°C, with a 10–14 hour light-dark cycle. All procedures were approved by the ethics committee for animal experiments of the University of Leuven.

**In vivo studies: breath test for gastric emptying**

**Animal preparation**

Standard commercial mouse chow (4352 Muracon G; Nutreco Belgium NV, Gent, Belgium) (4.5% fat, 4% cellulose, 21% proteins, 1.404 kcal/g) was available ad libitum until the evening before the test. At 5 pm food was removed and the test was started at 11 am the following day. A wiremesh plate was inserted into the bottom of the cage to avoid coprophagia during the period of fasting. Tap water was freely available at all times, except during the test.

**Test meal**

The solid test meal consisted of 0.1 g of baked scrambled egg yolk, doped with 0.01 pCi 14C octanoic acid sodium salt (American Radiolabeled Chemicals Inc, St Louis, Missouri, USA), and mixed with 0.1 g of standard mice chow. Tap water was added and mixed to form a homogenous paste.

Before the start of the experiments, fasted mice (18 hours overnight) were trained twice weekly (three day intervals), for two weeks (four times), on a fixed time schedule, to eat spontaneously the test meal (without radioactive marker) within 60 seconds.

**Breath test procedure: CO2 sampling**

On the experimental day, fasted mice (n = 6) were injected intraperitoneally with the compound of interest and placed individually in an airtight tube adapted with an inlet valve through which continuous airflow (80% N₂, 20% O₂, 360 ml/min) passed, while the air outflow was bubbled through a vial containing the CO₂ trapper tetramethylammonium hydroxide (1.3 mmol) (Acros, Geel, Belgium) to capture expired CO₂. The tetramethylammonium hydroxide solution (1.3 mmol) (Acros, Geel, Belgium) to capture expired CO₂. The tetramethylammonium hydroxide solution (1.3 mmol) (Acros, Geel, Belgium) to capture expired CO₂. The tetramethylammonium hydroxide solution (1.3 mmol) (Acros, Geel, Belgium) to capture expired CO₂.

After one hour of equilibration at optimal stretch (0.75 g), the stomach was removed and rinsed with ice cold saline. Circular muscle strips, freed from mucosa (length 10–15 mm, width 0.5 mm) were cut from the fundus and suspended vertically in an organ bath filled with Krebs solution (120.9 mM NaCl, 2.0 mM NaH₂PO₄, 15.5 mM NaHCO₃, 5.9 mM KCl, 1.25 mM CaCl₂, 1.2 mM MgCl₂, and 11.5 mM glucose) warmed at 37°C and gassed with 95% O₂/5% CO₂.

After one hour of equilibration at optimal stretch (0.75 g), the stomach was removed and rinsed with ice cold saline. Circular muscle strips, freed from mucosa (length 10–15 mm, width 0.5 mm) were cut from the fundus and suspended vertically in an organ bath filled with Krebs solution (120.9 mM NaCl, 2.0 mM NaH₂PO₄, 15.5 mM NaHCO₃, 5.9 mM KCl, 1.25 mM CaCl₂, 1.2 mM MgCl₂, and 11.5 mM glucose) warmed at 37°C and gassed with 95% O₂/5% CO₂. Reproducibility of the contractile response to acetylcholine (100 µM) was checked first and then electrical field stimulation (EFS) was applied via two parallel platinum rod electrodes using a Grass S88 stimulator. Frequency spectra (0.5, 1, 2, 4, 8, 16, 32 Hz) were obtained by pulse trains (duration 1 ms, train 10 s, 6 V). Voltage was kept constant using a Med Lab Stimu-Splitter II (Med Lab, Loveland, Colorado, USA). Each consecutive pulse train was followed by a 90 second interval. Mechanical responses in the smooth muscle strips were measured using an isometric force transducer/amplifier (Harvard Apparatus, Inc., South Natick, Massachusetts, USA) and stored on computer for analysis.

**Protocols**

The time interval between the two breath tests was set at three or four days. Each group of mice first underwent a control breath test (saline injection), followed by three consecutive breath tests (compound of interest) and again a control breath test. The following compounds were injected intraperitoneally 30 minutes before mice received the test meal: bethanechol (20 mg/kg), ghrelin (1–150 nmol/kg), GHRP-6 (6–150 nmol/kg), or capromorelin (6–150 nmol/kg). The effect of the GHS-R agonists was compared with the mean of the control breath tests given before and after injection of the GHS-R agonists.

Modulation of the effect of the GHS-R agonists by pharmacological blockers was tested by intraperitoneal administration of atropine (1 mg/kg), L-NAME (50 mg/kg), or D-Lys³-GHRP-6 (5.6 µmol/kg) 15 minutes before the GHS-R agonists.

**Data analysis**

By plotting the excreted radioactive CO₂ against time, a ¹⁴CO₂ excretion curve was constructed. Using least squares analysis, the excretion curve was fitted to two mathematical equations:

**Equation 1:** \( y = \frac{mkbe^{kt}}{1-e^{kt}} \)

**Equation 2:** \( y = at^{b}e^{ct} \)

where \( y \) is the percentage of ¹⁴CO₂ excretion in breath per hour, \( t \) is the time in hours; \( m, k, b, a, \) and \( c \) are regression estimated constants, with \( m \) the total amount of ¹⁴CO₂ recovered when time is infinite.

**In vitro contractility measurements**

Mice were sacrificed by cervical dislocation, and the stomach was removed and rinsed with ice cold saline. Circular muscle strips, freed from mucosa (length 10–15 mm, width 0.5 mm) were cut from the fundus and suspended vertically in an organ bath filled with Krebs solution (120.9 mM NaCl, 2.0 mM NaH₂PO₄, 15.5 mM NaHCO₃, 5.9 mM KCl, 1.25 mM CaCl₂, 1.2 mM MgCl₂, and 11.5 mM glucose) warmed at 37°C and gassed with 95% O₂/5% CO₂.

**Figure 1** Effect of ghrelin on gastric emptying in mice, as determined by the ¹⁴C octanoic breath test. Typical CO₂ excretion curves obtained after ingestion of a solid meal enriched with ¹⁴C octanoic acid, 30 minutes after intraperitoneal injection of ghrelin (75 nmol/kg) or 0.9% NaCl in the same mouse.
In vivo study

Development of the 14C octanoic acid breath test in mice

Our group has pioneered the breath test for measurement of gastric emptying. For the purpose of this study, the test was adapted for use in mice. Instead of the sampling procedure used in humans, we captured all excreted CO2 by placing the mice in an airtight tube. Continuous airflow was passed through the tube, and bubbled through a vial containing CO2 trapper. Our group has developed the 14C octanoic acid breath test in mice.

Figure 2  Intraindividual variations in gastric emptying parameters (T1/2 and Tlag) in mice. Mice were injected with 0.9% NaCl (0.2 ml intraperitoneally) on five different experimental days (days 0, 3, 15, 25, and 35), 30 minutes before the start of the 14C octanoic breath test, and the effect on T1/2 and Tlag was determined. Values are mean (SEM) of 12 mice. No significant differences were found.

Figure 3 Interindividual variations in gastric emptying parameters (T1/2 and Tlag) in mice. T1/2 and Tlag were determined from the CO2 excretion curves in 36 mice after intraperitoneal injection of 0.9% NaCl 30 minutes before the start of the 14C octanoic breath test. Between mice the coefficient of variation (CV) was 32% for T1/2 and 41% for Tlag with means of 77 minutes and 39 minutes, respectively.

Figure 4 Effects of bethanechol, atropine, and Nω-nitro-L-arginine methyl ester hydrochloride (L-NAME) on gastric emptying parameters in mice. Mice underwent three consecutive breath tests consisting of subcutaneous injection of 0.9% NaCl followed by bethanechol (20 mg/kg), atropine (1 mg/kg), or L-NAME (50 mg/kg) and then 0.9% NaCl again. The effect on T1/2 (A) and Tlag (B) was calculated from the CO2 excretion curves of the control and drug treated mice. Results are mean (SEM) of 6–12 mice. *p<0.05, **p<0.01 versus saline treatment.

Statistics

All data are presented as mean (SEM). Intraindividual variations within mice were analysed by one way repeated measurements ANOVA analysis. The dose dependent effect of the GHS-R agonists on gastric emptying parameters was investigated by two way ANOVA analysis with one repeated measurement factor (saline v drug). In the case of significant dose factor effects, univariate tests of significance for planned comparisons were performed. The effect of pharmacological agents on gastric emptying induced by capromorelin was analysed by one way repeated measurements ANOVA analysis followed by univariate tests of significance for planned comparisons.

The effect of GHS-R agonists on EFS induced contractile responses was investigated by two way ANOVA analysis, with two repeated measures factors (agonist, frequency). In case of significant factor effects, preplanned tests with contrasts were performed to locate pairs of factor levels with significant differences in the examined variables.

All data were analysed with Statistica 6.0 (StatSoft, Inc, Tulsa, Oklahoma, USA) and significance was accepted at a p value of <0.05.

RESULTS

Development of the 14C octanoic acid breath test in mice

Our group has pioneered the breath test for measurement of gastric emptying. For the purpose of this study, the test was adapted for use in mice. Instead of the sampling procedure used in humans, we captured all excreted CO2 by placing the mice in an airtight tube. Continuous airflow was passed through the tube, and bubbled through a vial containing CO2 trapper. Details are described in the methods section. Excretion of 14CO2 by mice fed with a test meal labelled with 14C octanoic acid showed an initial rapid increase with a peak value after approximately 50 minutes, followed by a slower decrease and a return to baseline after about four hours (fig 1). The potential of this test to study the effect of ghrelin agonists on gastric emptying was evaluated by determining the effect of intraperitoneal injection, day to day variability, and effect of compounds known to affect emptying rate.
Intraperitoneal injection could be experienced as a stressful event. Therefore, in the first series of experiments, a breath test was performed in 12 mice with and without intraperitoneal injection of saline ($0.2 \text{ ml/mouse}$). Neither $T_{1/2}$ (77.6 (6.5) vs 83.6 (5.5) minutes; $p = 0.54, n = 12$) nor $T_{\text{lag}}$ (35.4 (5.2) vs 33.2 (2.3) minutes; $p = 0.60, n = 12$) differed significantly between saline injected and non-injected mice.

Secondly, in order to evaluate the variability of the test, gastric emptying parameters were compared in 12 mice injected with saline on five different days over a time period of 35 days. Analysis of variance did not reveal significant day variations within mice for $T_{1/2}$ ($p = 0.19$) or $T_{\text{lag}}$ ($p = 0.60, n = 12$) differed significantly between saline injected and non-injected mice.

Thirdly, the effect of pharmacological agents known to enhance (bethanechol) or inhibit (atropine, L-NAME) gastric emptying in mice was tested. The muscarinic receptor agonist bethanechol (20 mg/kg intraperitoneally) significantly accelerated $T_{1/2}$ (from 70.4 (6.3) to 37.5 (5.2) minutes; $p<0.05$) and $T_{\text{lag}}$ (34.1 (3.8) to 20.9 (5.2) minutes; $p<0.05$). Diarrhoea occurred in all mice tested, as previously reported. The nitric oxide synthase inhibitor L-NAME (50 mg/kg intraperitoneally) significantly lengthened $T_{1/2}$ and $T_{\text{lag}}$. Data are summarised in fig 4.

**Effect of ghrelin, GHRP-6, and capromorelin on gastric emptying**

As illustrated in fig 1, intraperitoneal injection of ghrelin (75 nmol/kg) shifted the CO$_2$ excretion curve to the left and upwards, reflecting a shortening of $T_{1/2}$ (from 82.5 minutes to 36.1 minutes) and of $T_{\text{lag}}$ (from 39 minutes to 20.4 minutes). The dose dependency of the effect of ghrelin was tested by administration of different doses of ghrelin, ranging from 1 to 150 nmol/kg. The minimal effective dose that accelerated gastric emptying was 30 nmol/kg. The dose-response curve was bell-shaped, reaching a maximum for $T_{1/2}$ at 90.6 (16.3) nmol/kg and for $T_{\text{lag}}$ at 96.6 (19.8) nmol/kg (fig 5). Des-octanoylated ghrelin, tested at 50 and 150 nmol/kg, did not affect gastric emptying (data not shown). GHRP-6 and capromorelin were equipotent with ghrelin, as the maximum effect on $T_{1/2}$ was reached at comparable concentrations of 75 (5.5) nmol/kg for GHRP-6 and 106.5 (18.5) nmol/kg for capromorelin. Values for $T_{\text{lag}}$ were also comparable (fig 5).

**Pharmacology**

The effect of capromorelin on gastric emptying was characterised pharmacologically. In the presence of atropine (1 mg/kg), which lengthened $T_{1/2}$ from 85.5 (8.1) minutes to 142.3 (20.6) minutes, capromorelin failed to accelerate gastric emptying ($T_{1/2}$, 112.4 (18.3) minutes) significantly ($p = 0.11$ (fig 6). Similarly, capromorelin did not shorten $T_{\text{lag}}$, significantly in atropine treated mice (data not shown). Capromorelin was also unable to reverse the inhibition of...
gastric emptying due to pretreatment with L-NAME (50 mg/kg) (Fig 6). Pretreatment of mice with D-Lys3-GHRP-6, a putative GHS-R antagonist, significantly (p<0.01) delayed gastric half emptying from 82.7 (9.2) minutes to 201.6 (35.5) minutes and Tlag from 40.4 (4.4) to 121.2 (19.9) minutes (p<0.01). Under these conditions, capromorelin (75 nmol/kg) shifted the CO2 excretion curve to the left and shortened T1/2 to 99.8 (18.0) minutes (p = 0.051 compared with D-Lys3-GHRP-6) (Fig 7). Similar changes in the CO2 excretion curves were also observed with ghrelin and GHRP-6 in D-Lys3-GHRP-6 treated mice (data not shown).

In vitro study
Effect of GHS-R agonists on unstimulated preparations
Fundic strips of mice showed no spontaneous contractile activity but responded with a sustained contraction to 100 μM acetylcholine. Ghrelin (1 μM), GHRP-6 (1 μM), and capromorelin (1 μM) did not produce any responses (contraction or relaxation). However, higher concentrations of GHRP-6 (10 μM) caused a slowly developing transient contraction (9/13 strips), reaching a plateau within four minutes and recovering to the resting level after 7–8 minutes of application. This elevation in muscle tone was 19.9 (3.9)% of the response to 100 μM acetylcholine.

Effect of GHS-R agonists on neural responses in the fundus
EFS of mouse fundic strips caused frequency dependent weak relaxations between 2 Hz and 32 Hz during the stimulation period. An example is shown in Fig 8. In the presence of L-NAME (300 μM), relaxations became strong contractions over the entire frequency range. These contractions were completely blocked by atropine (5 μM) at low frequencies (0.5–4 Hz) but at higher frequencies (8–32 Hz) small atropine resistant contractions remained. All responses were abolished in the presence of tetrodotoxin (1 μM). Representative tracings are shown in Fig 8. Reversal of relaxation was also observed after treatment with the cholinesterase inhibitor hyposystigmine (100 nM).

Under normal conditions, pretreatment with GHRP-6 (1 μM) or ghrelin (1 μM) did not affect EFS induced relaxations (Fig 9). However, in the presence of L-NAME (300 μM), ghrelin (1–32 Hz), GHRP-6 (1–32 Hz), and capromorelin (2–32 Hz) significantly increased EFS induced contractions (Fig 9). No significant difference was observed between the maximal changes in tension induced by the respective GHS-R agonists at the different frequencies (ghrelin 1.05 (0.24) g/mm² at 8 Hz; GHRP-6 1.48 (0.44) g/mm² at 16 Hz; capromorelin 1.10 (0.23) g/mm² at 16 Hz).

DISCUSSION
In the present study we have demonstrated that ghrelin and the synthetic GHS-R agonists GHRP-6 (peptide) and capromorelin (non-peptide) accelerate gastric emptying of solids. It is the first report demonstrating the gastroprokinetic action of synthetic peptide and non-peptide GHS-R agonists in mice. The effect may be mediated through potentiation of peripheral cholinergic pathways. A variety of techniques have been used to assess gastric emptying in small laboratory animals. In most techniques, the animals are sacrificed and the content of the stomach and intestine is analysed by measuring its radioactivity, counting the remaining number of glass beads, or measuring the concentration of a marker, such as Evans blue or phenol red by spectrophotometry. Recently, non-invasive techniques such as the 14C octanoic breath test and whole body gamma scintigraphy have found wide application in humans, and they have also been adapted to small animals.20–22

We adapted the 14C octanoic breath test20 for use in mice. The use of 14C octanoic acid instead of 13C octanoic acid allows for a simpler and more sensitive detection technique. As implemented in mice, it almost eliminates sampling errors, as the total amount of CO2 is collected. The test allows serial measurements in the same mice, is non-invasive, and does not require handling or restraint of the animals in contrast with the scintigraphic test. Using the same mathematical analysis as that developed in humans, we showed that the gastric emptying parameters T1/2 and Tlag were not affected by injection of intraperitoneal saline, a stressfull event for mice, and showed little day to day
Gastroprokinetic effects of ghrelin agonists in mice

Gastric emptying is a complex process, involving excitatory and inhibitory nerves, which may contribute to both acceleration and retardation of the emptying process. For example, L-NAME, which blocks inhibitory nitricergic nerves, delays gastric emptying, probably by interfering with gastric accommodation and pyloric relaxation. The effect of ghrelin may therefore involve both excitatory and inhibitory pathways, as suggested by the inability of ghrelin to overcome the delay induced by L-NAME and atropine.

Previous studies on the effect of ghrelin on gastric motility demonstrated the involvement of vagal and central ghrelin receptors. Thus the effect of ghrelin on gastric motor activity and gastric emptying was blocked by atropine and vagotomy in rats and mice. Fujino and colleagues showed that peripheral ghrelin may stimulate fasted small intestinal motor activity in rats by activating neuropeptide Y neurones in the brain through receptors on vagal afferents. In addition, expression of the ghrelin receptor in the rat nodose ganglion has been confirmed using reverse transcription-polymerase chain reaction, direct sequencing, in situ hybridisation, histochemistry, and electrophysiology. Recent data indicate that ghrelin may also activate local pathways in the enteric nervous system. Ghrelin increases electrically evoked cholinergic neural responses in rat stomach strips and activates a subset of myenteric neurones in the guinea pig jejunum. There is also morphological evidence for the presence of ghrelin and ghrelin receptors in the myenteric plexus of the guinea pig ileum. Such local pathways may form a backup system activated under abnormal conditions or during pharmacological stimulation. For example, Fujino and colleagues showed that in rats, the motor effects in vivo are blocked by vagotomy, but that following vagotomy a local mechanism becomes operational. In the present study, we provided evidence that in mice, not only ghrelin but also GHRP-6 and capromorelin can increase electrically induced cholinergic contractions, masked by nitricergic nerves, without affecting smooth muscle tonus. Recently, ghrelin was shown to activate a subset of myenteric neurones.

Gastroprokinetic effects of ghrelin agonists in mice

Figure 9 Effects of ghrelin (A), growth hormone releasing peptide 6 (GHRP-6) (B), and capromorelin (C) on electrical field stimulation induced mechanical responses of mice fundic strips. Muscle strips were electrically stimulated (0.5–32 Hz) preceding and during incubation with NG-nitro-L-arginine methyl ester hydrochloride (L-NAME 300 μM) or capromorelin (1 μM), and the tension of the responses was measured. Results are mean (SEM) of five strip preparations from different mice. *p<0.05, **p<0.01 versus the frequency spectrum in the presence of L-NAME in the same strip preparation.
to induce release of nitric oxide in the rat stomach and in our study a nitrergic pathway could be involved in acceleration of gastric emptying as the prokinetic effect in vivo was lost in the presence of L-NAMe. However, in our in vitro data do not provide evidence that nitric oxide mediated relaxation could be involved in gastric emptying rate of liquids and solids in mice. J Neurol 1994;358:23–41.

Gastric motor effects of peptide and non-peptide ghrelin agonists in mice in vivo and in vitro
