Protein kinase C isozymes regulate matrix metalloproteinase-1 expression and cell invasion in Helicobacter pylori infection

Olga Sokolova,1 Michael Vieth,2 Michael Naumann1

ABSTRACT

Background Protein kinase C (PKC) signalling is often dysregulated in gastric cancer and therefore represents a potential target in cancer therapy. The Gram-negative bacterium Helicobacter pylori, which colonises the human stomach, plays a major role in the development of gastritis, peptic ulcer and gastric adenocarcinoma.

Objective To analyse the role of PKC isozymes as mediators of H pylori-induced pathogenesis.

Methods PKC phosphorylation was evaluated by immunoblotting and immunohistochemistry. Gene reporter assays, RT-PCR and invasion assays were performed to assess the role of PKC in the regulation of activator protein-1 (AP-1), matrix metalloproteinase-1 (MMP-1) and the invasion of H pylori-infected epithelial cells.

Results H pylori induced phosphorylation of PKC isozymes α, δ, θ in AGS cells, which was accompanied by the phosphorylation of PKC substrates, including PKCα and myristoylated alanine-rich C kinase substrate (MARCKS), in a CagA-independent manner. Phospholipase C, phosphatidylinositol 3-kinase and Ca2+ were crucial for PKC activation on infection; inhibition of PKC diminished AP-1 induction and, subsequently, MMP-1 expression. Invasion assays confirmed PKC involvement in H pylori-induced MMP-1 secretion. In addition, analysis of biopsies from human gastric mucosa showed increased phosphorylation of PKC in active H pylori gastritis and gastric adenocarcinoma.

Conclusion The targeting of certain PKC isozymes might represent a suitable strategy to interfere with the MMP-1-dependent remodelling of infected tissue and to overcome the invasive behaviour of gastric cancer cells.

INTRODUCTION

Serine/threonine kinases of the protein kinase C (PKC) family are important molecules in the regulation of cellular differentiation, proliferation, apoptosis, adhesion and migration.1 PKC signalling participates in the regulation of gastric acid production2 and is often dysregulated in gastric cancer.3,4 Several PKC isoforms have been implicated in invasion and metastasis; however, the molecular mechanisms are still not well understood.

The PKC family consists of at least 10 isozymes classified into three main groups (figure 1A). Conventional PKC (cPKC) α, βI, βII and γ bind Ca2+ and phosphatidylserine and require diacylglycerol (DAG) for further activation. The novel PKC (nPKC) δ, ε, θ, η possess a functional C1 domain, but their C2-like domains do not contain Ca2+-binding residues. Therefore, nPKC isozymes are regulated by DAG and phosphatidylserine, but not by Ca2+. The atypical PKCs (PKCζ and PKCδ)
lack both functional C1 and C2 domains and are neither Ca\(^{2+}\)- nor DAG-dependent.\(^5\)

In addition to their regulation by lipid second messengers, phosphorylation of conserved Ser/Thr sites within the C3 domain plays an important role in stabilisation and catalytic competence of PKC. Phosphorylation allows for the binding of the kinase domain to pseudosubstrate (within their own regulatory domain) to keep the enzyme in a latent conformation or promotes PKC binding to real substrates for full activation.\(^6\)

*Helicobacter pylori* colonises the stomach in at least 30–50% of the world’s population and increases the risk of peptic ulcers and gastric cancer. *H pylori* secretes effector molecules (lipo-polysaccharide, VacA) into the extracellular space or injects them (CagA, muropeptides) directly into the cytoplasm of the host cell via the type IV secretion system (T4SS).\(^7\) Therby *H pylori* controls the inflammatory, proliferative, pro- and anti-apoptotic cellular statuses.\(^8\)

Other bacterial factors, including adhesins, urease, flagellae and components of the outer membrane, also contribute to the colonisation of the gastric mucosa.\(^9\) Bacteria–gastric epithelial cell interactions lead to induction of a range of matrix metalloproteinases (MMPs).\(^10\) MMPs participate in extracellular matrix (ECM) remodelling, the cleavage of cell adhesion molecules (eg, E-cadherin) and the processing and activation of chemoattractants and ligands for growth factor receptors,\(^12\) which leads to an increase in epithelial permeability and promotes leucocyte infiltration into the gastric mucosa.

The involvement of PKC in many cellular functions and in pathophysiology, for example, carcinogenesis, suggests that PKC may play a role in *H pylori* infection. However, very few studies have addressed the activation of PKC during *H pylori* infection. Obst et al\(^13\) have demonstrated the translocation of PKCa to the plasma membrane in *H pylori*-infected AGS cells, and Brandt et al\(^14\) have shown the *H pylori*-induced phosphorylation of PKCa and PKCd in these cells. There is only limited knowledge about the functional role of PKC in *H pylori* infection. By using a number of inhibitors, PKC has been demonstrated to participate in *H pylori*-induced alteration of the barrier properties of the

**Figure 1** *H pylori* activates protein kinase C (PKC). (A) The protein domains of the PKC family members, showing the pseudosubstrate (dark blue rectangle), the C1 domain that binds DAG, phosphatidylserine and phorbol esters, the C2 domain that binds Ca\(^{2+}\) or PIP2 (in the case of nPKC), and the C3 kinase domain. Also shown in orange are the conserved Ser/Thr residues phosphorylated during *H pylori* infection. (B) AGS cells were infected with *H pylori* P1 wt, cagA or virB7 mutants for different periods of time or were stimulated with PMA for 1 h. Cell lysates were analysed by immunoblotting using antibodies as indicated. Unphosphorylated PKC\(\alpha\) and PKC\(\mu\) served as loading controls. (C) Analysis of phosphorylation of PKC substrates in cells treated as described in (B). GAPDH was immunodetected to show equal protein amounts in the cell samples.
epithelium and NF-κB-dependent cyclooxygenase-2 expression in gastric epithelial cells. Contradictory data exist concerning PKC involvement in IL-8 regulation in the gastric epithelium on infection.17 18

The aim of this study was to investigate the mechanisms and the functional consequences of H. pylori-induced PKC activation. We show here that H. pylori induces PKC in gastric epithelial cells, which involves the classical upstream PKC regulators PI3K, phospholipase Cγ (PLCγ) and Ca²⁺. Our data demonstrate for the first time that PKC contributes to c-Fos expression and activator protein-1 (AP-1) induction, which leads to matrix metalloproteinase-1 (MMP-1) up-regulation on H. pylori infection. In addition, we show the induction of PKC phosphorylation in gastric mucosa tissue from patients with active H. pylori gastritis and gastric adenocarcinoma.

MATERIALS AND METHODS
The antibodies and the chemicals used in this work are described in supplementary tables 1 and 2. The descriptions of the procedures for preparation of cell lysates, immunoblotting, immunofluorescence, immunohistochemistry, RNA isolation, RT-PCR, transfection, the reporter gene assay, the invasion and wound healing assays are provided in the online data supplement.

Cell culture and bacteria
AGS (ATCC) and HCA-7 (European Collection of Cell Cultures, Salisbury, UK) cells were grown in RPMI 1640 medium (PAA Laboratories, Pasching, Austria) supplemented with 10% fetal calf serum (FCS) and penicillin/streptomycin. Cells derived from human prenatal stomach tissue (HSC; Innoprot, Derio, Spain) were cultured as described previously.19 Sixteen hours before infection, the cell medium was replaced with fresh RPMI 1640 supplemented with 0.5% FCS.

The wild-type (wt) H. pylori P1 strain and isogenic mutants cagA and virB7 or P12 wt and its VacA deficient mutant were cultured for 48–72 h, as described previously, and added to AGS cells at a multiplicity of infection of 100. In a set of experiments, the bacteria were loaded into the upper inserts of a 100 mm Transwell plate (Costar, Corning, New York, USA), and thereby separated from AGS cells cultured in the bottom chamber by a polycarbonate membrane (0.4 μM pore size).

Patients and tissue samples
Stomach biopsy specimens were obtained from 160 patients (age range 19–96 years) according to the recommendations of the updated Sydney System and were examined by the same experienced gastrointestinal pathologist who was blinded to the clinical and endoscopic data. Biopsies were stained with H&E, and also with Warthin–Starry–silver stain for detection of H. pylori. Histological features of the gastric mucosa, including inflammation and atrophy were scored according to the updated Sydney System. Diagnosis of neoplasia was made according to the WHO classification 2010.

Statistical analyses
Statistical analyses of the results were performed using the Student t test. The data are expressed as the mean fold changes from at least three separate experiments ± SEM with the value of the control arbitrarily normalised to 1; p<0.05 was considered significant. The immunohistochemical data were analysed using analysis of variance (IBM SPSS 18). The statistical decisions were two-tailed with a critical probability of α=5% using a post-hoc t-test.

RESULTS
H. pylori induces phosphorylation of PKCα, PKCδ, PKCθ and PKCη
While studying the effect of H. pylori on PKC, a transient increase in phosphorylation was observed within 30 min for PKCε (Ser657), within 30–60 min for PKCθ (Thr505) and within 3–6 h for PKCθ (Thr538) following infection with P1 wt strain (figure 1A,B). Phorbol myristoyl acetate (PMA), a membrane-permeable substitute for DAG, was used as a positive control. To investigate the involvement of H. pylori virulence factors in PKC phosphorylation, AGS cells were infected with H. pylori mutants deficient in either CagA or VirB7 protein, which is required for the integrity of the T4SS. Both mutants adhered equally to AGS cells (data not shown). The cagA, but not the virB7, mutant induced PKCα phosphorylation. No differences between the wt, cagA or virB7 mutants were observed for PKCδ or PKCθ phosphorylation (figure 1B). Thus, H. pylori induced transient phosphorylation of cPKCα in a CagA-independent, but T4SS-dependent manner; however, nPKCδ and nPKCθ were induced in a CagA- and T4SS-independent manner. No changes were detected in the Ser497, Ser729 and Thr410/Thr403 phosphorylation of AGS cells with H. pylori induced phosphorylation of PKCη, a nPKC target, at the sites that correlate closely with kinase activity (figure 1B).

Intracellular localisation plays an important role in PKC function.5 6 Treatment with H. pylori (or PMA) led to an accumulation of phosphorylated PKCα in the membranes and nuclei of AGS cells (supplementary figure 1A–C). In contrast to PMA, H. pylori promoted no translocation of PKC isoforms δ and θ from the cytosol to membranes and nuclei (supplementary figure 1B).

To analyse the phosphorylation of PKC substrates, we used an antibody to phosphorylated Ser residues surrounded by Arg or Lys at the −2 or +2 positions and a hydrophobic residue at the +1 position. Figure 1C shows that wt and CagA-deficient H. pylori induced a strong increase in Ser-phosphorylation of PKC substrates in AGS cells. Infection with the virB7 mutant led to a less prominent phosphorylation of PKC substrates. Actin-binding protein myristoylated alanine-rich C kinase substrate (MARCKS), a downstream target of cPKC and nPKC, was phosphorylated in cells infected with the wt and cagA mutant of H. pylori within 1 h. Again, phosphorylation induced by the virB7 mutant was less prominent (figure 1C).

The P12 wt and vacA mutant of H. pylori, as well as the P1 wt, induced the phosphorylation of PKC substrates. Heat-inactivated bacteria were not able to move, settle on the surface of the AGS cells (data not shown), or induce the phosphorylation of PKC substrates (supplementary figure 1D). Additionally, experiments using Transwell plates demonstrated that H. pylori does not induce any phosphorylation of PKC substrates in the absence of direct contact with AGS cells (supplementary figure 1D). Thus, the adherence of living H. pylori to host cells is required for PKC induction.

To study PKC activity in vivo, human gastric biopsies were analysed by immunohistochemistry. A pan-specific antibody, which recognises phosphorylation within the activation loop (Ser497, Ser505 and Ser538 of PKCα, PKCδ and PKCθ, respectively), was used (supplementary figure 2). PKC phosphorylation was determined in the gastric tissue of patients with H. pylori-active H. pylori infection.
Helicobacter pylori

gastritis or gastric adenocarcinoma, but not in the non-infected normal gastric mucosa (table 1).

In the non-infected group, 100% of specimens demonstrated an immunoreactivity less than the median of all variables (8 cells/hpf). In the ‘HP-gastritis’ and ‘adenocarcinoma’ groups, 52.6% and 81.5% of specimens, respectively, were strongly positive for phospho-PKC. In the studied biopsies, no changes in the expression of PKCβ were observed (supplementary table 3).

H pylori-induced activation of PKC involves PLCγ1, Ca2+, tyrosine kinases and PI3K

The PKC activator DAG is mainly produced from phosphatidylinositol 4,5-bisphosphate (PIP2) or phosphatidylcholine (PC) through direct cleavage with phosphatidylinositol-specific PLC (PI-PLC) or PC-specific PLC (PC-PLC), respectively.25 Pretreatment of AGS cells with U73122 or D609, selective inhibitors of PI-PLC or PC-PLC, respectively, reduced the phosphorylation of PKC substrates and MARCKS following infection (figure 2A). Thus, the H pylori-induced activation of PKC involves PC-PLC and PI-PLC.

PI-PLC comprises a group of Ca2+-dependent enzymes, including PLCβ, γ, δ, ε, ζ and PLCη families.26 PLCβ and PLCγ are the most studied isozymes. PLCβ (four isoforms) is induced in response to the activation of G protein-coupled transmembrane receptors. PLCβ3 is ubiquitous, whereas PLCβ1 is not expressed in the stomach; PLCβ2 and PLCβ4 are highly expressed in cells of haematopoietic origin as well as in the cerebellum and retina.27 PLCγ (two isoforms) is stimulated on activation of receptor and non-receptor tyrosine kinases.28 PLCγ1 is widely distributed, whereas PLCγ2 is expressed primarily in cells of haematopoietic origin. To determine the role of particular isoforms in infected cells, transient transfections with siRNAs targeting either PLCγ1 or PLCβ3 were performed. In contrast to PLCβ3, PLCγ1 depletion suppressed H pylori-induced phosphorylation of PKC substrates, including MARCKS (figure 2B,C). Therefore, PI-PLCγ1 contributes to PKC regulation on H pylori infection.

H pylori has been shown to provoke a CagA-independent increase of (Ca2+), in gastric epithelial cells.29 Investigating the role of Ca2+ in PKC activation, we found that the phosphorylation of PKC substrates was dramatically reduced on treatment of the cells with the Ca2+-chelator BAPTA-AM prior to infection (figure 2D). Additionally, the tyrosine kinase inhibitor genistein and PI3K inhibitor LY294002 diminished the phosphorylation of PKC substrates and MARCKS (figure 2E). Taken together, these data indicate that Ca2+, tyrosine kinases and PI3K are involved in PKC regulation during infection of epithelial cells with H pylori.

To substantiate that the phosphorylation of PKC substrates reflects PKC catalytic activity, bisindolylmaleimide I (BIS I), a selective inhibitor of conventional and novel PKC, was used. The phosphorylation of PKC substrates and MARCKS in response to H pylori or PMA was completely abolished in BIS I-treated cells (figure 2F). Importantly, BIS I demonstrated no toxicity towards H pylori, in contrast to many other PKC inhibitors, including rottlerin (supplementary figure 3) and calphostin C (data not shown).

Inhibition of PKC reduces MMP-1 expression in H pylori-infected cells

While studying the role of PKC activation, we observed that BIS I significantly inhibited MMP-1 gene expression (figure 3A) and protein accumulation (figure 3B) both in H pylori-infected and in PMA-treated AGS cells. MMP-1 expression following infection with P12 wt reached a maximum at 6 h post-infection (figure 3C), and MMP-1 accumulated in the membranes and nuclei of infected cells (figure 3D). MMP-1 gene up-regulation depended on the strain used for infection, and the P1 strain was less potent in inducing MMP-1 than the P12 strain (figure 3A,E). The cagA H pylori mutant was as effective as the wt, but the virB7 mutant up-regulated MMP-1 to a lesser extent (figure 3E,F).

Importantly, BIS I suppressed the MMP-1 expression induced by P12 wt in both the human HCA-7 colon cancer cell line and in primary stomach cells (supplementary figure 4A). Importantly, in both cell systems H pylori P12 wt induces PKC, which leads to phosphorylation of PKC substrates (supplementary figure 4B). HSC constitutively express mRNA from Muc-5ac and Muc-6 genes and stain positive for H+,K+-ATPase and pan-cytokeratins (supplementary figure 4C), which is consistent with normal gastric epithelial cells.

PKC regulates MMP-1 by activating AP-1 transcription factor

The MMP-1 promoter is predominantly regulated by AP-1 (figure 4A).29 Infection with H pylori led to a 4.4-fold increase in AP-1 activity (figure 4B). A more pronounced effect on AP-1 activity was achieved by treatment with PMA (51.5-fold induction; figure 4B). Pretreatment of the cells with BIS I completely abolished PMA-induced and diminished H pylori-induced AP-1 transactivation (figure 4B). AP-1 is a dimer that consists of Fos (c-Fos, FosB, Fra-1, Fra-2) and Jun (c-Jun, JunD, JunB) proteins and is positively regulated by mitogen-activated protein kinases (MAPK) (figure 4C).30 H pylori has been shown to activate a heterodimer composed of c-Fos and c-Jun.31 While exploring the molecular mechanism of AP-1 activation, we observed a strong phosphorylation of ERK1/2, JNK1/2, p38, c-Jun, ATF-2, JNK up-stream kinase MKK4, and accumulation of c-Jun and c-Fos in both H pylori- and PMA-treated cells (figure 4D). BIS I abolished all of the effects of PMA and reduced H pylori-induced c-Fos and c-Jun up-regulation. Surprisingly, in the infected cells, BIS I had no effect on the phosphorylation of ERK, p38 or JNK, which are considered to be up-stream regulators of c-Fos and c-Jun (figure 4C,D). The infection of AGS cells with wt H pylori and mutants showed that c-Jun was expressed following infection with the virB7 mutant, but delayed in comparison to the wt, which is in agreement with a report by Ding et al.33 However, phosphorylation of JNK1/2 and p38 was clearly

*p<0.05 versus ‘non-infected’ group, as determined by the Dunnett t-test.
T4SS-dependent (supplementary figure 5). These results indicate that in *H. pylori*-treated cells, PKC is involved in up-regulation of the AP-1 members c-Fos and c-Jun, but the exact integrative mechanism and bacterial factors involved remain elusive.

Additionally, we found no accumulation of the AP-1 co-activator polyomavirus enhancer activator-3 (PEA3), which might promote MMP-1 expression in infected cells (data not shown).34 PKCα, PKCδ and PKCθ control *H. pylori*-induced MMP-1 expression through c-Fos

Given our results, which demonstrate that *H. pylori* induces phosphorylation of PKCα, PKCδ and PKCθ, the involvement of these isoforms in MMP-1 regulation was subsequently tested. Specific PKC-targeting siRNAs reduced MMP-1 mRNA (figure 5A) and protein expression (figure 5B) in the infected cells. Depletion of PKCδ and PKCθ, but not PKCα, partially inhibited induction of MMP-1 by PMA (figure 5A,B).

A prominent decrease of c-Fos expression in PKCδ siRNA-treated cells was observed when studying the signalling molecules involved in the activation of AP-1 in response to *H. pylori* (figure 5C). c-Jun expression and phosphorylation of c-Jun, ERK, JNK and MKK4 were not affected (figure 5C). These results suggest that PKCα, PKCδ and PKCθ contribute to c-Fos up-regulation during infection with *H. pylori*. In PMA-exposed cells, PKCδ depletion slightly affected the expression of c-Fos and c-Jun (figure 5C).

To confirm the crucial role of c-Fos in MMP-1 up-regulation, AGS cells were transfected with a c-Fos-targeting siRNA. On c-Fos knockdown, MMP-1 synthesis was diminished in both *H. pylori*- and PMA-treated cells (figure 5D). Thus, c-Fos represents an important mediator in PKC-regulated MMP-1 expression.

Overexpression of PKC leads to AP-1 activation

To substantiate that PKCα, PKCδ and PKCθ regulate AP-1 in AGS cells, gene reporter assays were performed (figure 5E). Overexpression of constitutively active PKCα, δ and θ led to the transactivation of the AP-1 reporter gene 48 h post-transfection (1.8-, 1.3- and 3.5-fold, respectively) and 72 h post-transfection (2.8-, 4- and 2.1-fold, respectively). Immunoblotting revealed an accumulation of c-Fos in cells overexpressing PKC, which correlated with AP-1 activity and MMP-1 accumulation, and was most prominent in PKCθ-overexpressing cells (figure 5F). PKC overexpression did not induce the accumulation or phosphorylation of c-Jun (figure 5F). Thus, the PKC isoforms α, δ and θ regulate c-Fos leading to AP-1 activation in gastric cells.

PKC promote invasion of AGS cells in *H. pylori* infection

To further analyse the role of PKC in MMP-1 secretion, invasion assays using collagen I-coated filters were performed. Figure 6A...
shows that co-culturing of AGS cells with *H pylori* led to enhanced cellular invasion, which was less prominent on infection with the *virB7* mutant strain compared to the wt and *cagA* strains. To assess the role of MMP-1 in *H pylori*-induced invasiveness, AGS cells were transfected with siRNA targeting MMP-1. Depletion of MMP-1 inhibited both basal and *H pylori*-induced MMP-1 expression in AGS cells (figure 6B) and suppressed invasion in response to *H pylori* (figure 6A). Treatment of the cells with the PKC inhibitor BIS I prior to infection markedly reduced the number of invading cells (figure 6C). Similar results were obtained for PMA.

Depletion of PKC_α, PKC_β and PKC_δ, which is crucial for MMP-1 production in response to *H pylori*, abolished transmigration of infected cells, indicating a functional role for these enzymes.

**Figure 3** *H pylori* up-regulates MMP-1 in a protein kinase C (PKC)-dependent manner. BIS I-treated or non-treated AGS cells were incubated with *H pylori* P12 wt, PMA (A–D) or *H pylori* P1 wt or the *cagA* and *virB7* mutants (E, F) for 3 h or for the indicated periods of time. MMP-1 expression was analysed by qRT-PCR (A, C, E) or immunoblotting (B, D, F). The graphs in (B) summarise the densitometric analysis of three independent immunoblots (experiments). GAPDH, occludin and histone H3 were immunodetected to show the appropriate fractionation and equal protein amounts in the cell samples. Bacterial lysate was used as a negative control. *p*<0.05, **p**<0.01 versus non-stimulated cells; #p<0.05, ##p<0.01 versus BIS I-free stimulated cells.

**Figure 4** *H pylori* up-regulates AP-1 in a protein kinase C (PKC)-dependent manner. (A) The composition of MMP-1 promoter. isozymes in invasion (figure 6D). Depletion of PKCα, PKCδ or PKCθ had a less prominent effect in PMA-treated cells (figure 6D). To confirm the regulatory role of PKCα, δ and θ in invasion, constitutively active isozymes were overexpressed. Figure 6E shows that PKC overexpression increased the number of invading cells. Taken together, these results indicate that MMP-1-dependent collagen I digestion involves PKC in H. pylori-infected cells.

Invasion is an integrative process that depends on the adhesive and migratory behaviours of cells, in addition to their proteolytic activity towards the ECM. Therefore, involvement of PKC in regulation of cellular motility was investigated using a wound healing assay. In contrast to PMA, the P1 and P12 strains of H. pylori did not stimulate wound healing (supplementary figure 6A,B). Treatment with H. pylori or PMA for 24 h slightly decreased the total number of AGS cells (data not shown). Thus, H. pylori-induced invasion depends mainly on the increased proteolytic activity of AGS cells. Bis I, but not siRNAs against PKCα, PKCδ or PKCθ, inhibited PMA-induced cell migration (supplementary figure 6A,C). Therefore, several PKC isozymes are engaged to stimulate both the proteolytic activity and migration of PMA-treated cells, leading to increased cell invasiveness.

In addition to the wound healing assay, the involvement of PKC in H. pylori-induced scattered phenotype was studied, and no effects of Bis I or PKC-specific siRNAs on cell morphology were found (supplementary figure 7). However, PMA-induced AGS cell spreading was completely blocked by Bis I but not by siRNAs against PKCα, PKCδ or PKCθ (supplementary figure 7).

**DISCUSSION**

The aim of this work was to investigate the activity and role of PKC isozymes in infected gastric epithelial cells. We show here that, on H. pylori infection, cPKCα is phosphorylated within its hydrophobic motif and accumulates in both membranes and nuclei, which might represent sources of DAG and PKCα-interacting proteins. Autophosphorylation of the hydrophobic motif of PKCα has been reported to stabilise the enzyme and to be triggered by the mammalian target of rapamycin complex 2 and HSP90. Further, our results demonstrate that nPKCs δ and θ are transiently phosphorylated within their activation loops in a T4SS-independent manner. This finding is consistent...
with reports that both \textit{H. pylori} cagPAI and the outer membrane protein OipA activate phosphatidylinositol kinase 1 (PDK-1),\textsuperscript{38} which phosphorylates the activation loop of PKC, leading to enzyme maturation and activation\textsuperscript{39} (figure 6F). In contrast to the study by Brandt \textit{et al}.,\textsuperscript{14} we did not detect any CagA-dependent PKC\textsubscript{50} phosphorylation at 6–9 h post-infection.

Activated PKC regulate their substrates, including MARCKS, vinculin and adducin.\textsuperscript{6 24} Our experiments demonstrate that \textit{H. pylori} causes phosphorylation of downstream targets of PKC, including MARCKS in a CagA- and VacA-independent manner. The phosphorylation of PKC substrates is less prominent during infection with the \textit{virB7} mutant strain. The most plausible model is that the phosphorylation of PKC substrates implicates a range of PKC isozymes that are activated independently of T4SS (eg, PKC\textsubscript{5} and PKC\textsubscript{8}) and via T4SS (eg, PKC\textsubscript{a}) (figure 6F).

For full activation, conventional and novel PKC require DAG, generated following PIP2 hydrolysis by PLCs. Here, we show that both PI-PLC and PC-PLC inhibitors reduce the phosphorylation of PKC substrates in \textit{H. pylori}-infected cells, with the PI-PLC inhibitor being more effective. Indeed, PI-PLC-dependent hydrolysis of PIP2 yields, in addition to DAG, inositol 1,4,5-trisphosphate (IP3).\textsuperscript{25 27} which provokes an increase of intracellular \textit{Ca}\textsuperscript{2+}. Thus, PI-PLC promotes activation of both DAG- and \textit{Ca}\textsuperscript{2+}-dependent PKC isozymes (figure 6F).

Within PI-PLCs, PLC\textsubscript{γ1} plays an important role in PKC activation, as shown here using PLC\textsubscript{γ1}-targeting siRNA. Additionally, PLC\textsubscript{γ1} activation in \textit{H. pylori}-infected gastric epithelial cells has been reported previously.\textsuperscript{20}

Our experiments using BAPTA-AM further confirm a contributory role of intracellular \textit{Ca}\textsuperscript{2+} in PKC activation on infection. As functional T4SS (but not CagA) is required for \textit{Ca}\textsuperscript{2+} release during \textit{H. pylori} infection,\textsuperscript{28} we propose that T4SS is implicated in the regulation of \textit{Ca}\textsuperscript{2+}-activated PKC isozymes. Consistently, phosphorylation of \textit{Ca}\textsuperscript{2+}-regulated PKC\textsubscript{a} is T4SS-dependent.

It has previously been shown that PI3K signalling is activated by \textit{H. pylori}.\textsuperscript{38 40} PI3K, which phosphorylates PIP2 and leads to PIP3 generation, has been implicated in PDK-1 activation. Here, PI3K inhibition diminished the phosphorylation of PKC in patients with \textit{H. pylori}-induced gastritis or gastric adenocarcinoma, which indicates that post-translational modifications of these enzymes may be crucial for \textit{H. pylori}-induced pathogenesis.

Our results demonstrating that \textit{H. pylori} induces the phosphorylation of PKC\textsubscript{a}, PKC\textsubscript{8} and PKC\textsubscript{5}, we focused on their role in infected gastric epithelial cells. All of these PKC isozymes are involved in regulation of the cytoskeleton, adherent junctions and barrier permeability in the gastrointestinal epithelium.\textsuperscript{41} PKC may play a role in the pathogenesis of \textit{H. pylori}-caused diseases by affecting the integrity of the gastric epithelium.\textsuperscript{15}
Gastric mucosa disturbances in response to \textit{H. pylori} implicates a range of MMPs, including MMP-1.\textsuperscript{10} MMP-1 not only degrades collagens I-III, VII, VIII and X, gelatin, and entactin,\textsuperscript{30} but also has functions extending beyond the degradation of the ECM components. For example, MMP-1 was found in the nucleus where it appears to confer resistance to apoptosis.\textsuperscript{42} Cytokines, growth factors and LPS induce MMP-1 synthesis via MAPK cascades in different cell types.\textsuperscript{53} 44 MMP-1 is often up-regulated in gastric ulcers and cancer.\textsuperscript{10} 45 Our data indicate that \textit{H. pylori} stimulates MMP-1 synthesis in gastric epithelial cells, which is in accordance with published data.\textsuperscript{11} 19 46 Although both P1 and P12 belong to the type I \textit{cagA}“\textit{vacA}”-\textit{kataA}“\textit{fleA}” \textit{strains}, P1 was less potent in inducing MMP-1 than the P12 strain; this finding requires further investigation. We found that MMP-1 accumulates in membranous structures and nuclei of infected cells. Further, our results show that similar to PKC activation, MMP-1 expression requires both functional T4SS and other T4SS-independent bacterial factors, for example, OipA.\textsuperscript{34} Using the PKC inhibitor BIS I or PKC-specific siRNAs, we discovered that PKC\textit{z}, PKC\textit{b} and PKC\textit{b} up-regulate MMP-1, leading to enhanced invasion by infected AGS cells. Importantly, we observed no significant enhancement of migration on infection. Therefore, it is apparent that \textit{H. pylori}-stimulated invasion depends mainly on the proteolytic, but not the migratory, activity of AGS cells. The inhibitory effect of BIS I on MMP-1 expression was not restricted to AGS cells and was also detected in tumour HCA-7 cells and non-cancerous HSC, which suggests that this represents a common phenomenon.

It is well established that PMA, which induces a sustained activation of almost all of the PKC isoforms, up-regulates MMP-1.\textsuperscript{45} In this study, PMA stimulated MMP-1 synthesis, invasion and migration of AGS cells. Depletion of one particular PKC isoform (eg. PKC\textit{b}) had a weak effect on these processes, probably because of a contributory role of intact PKC isoforms activated by PMA.

How does PKC regulate MMP-1? PMA has been reported to activate ERK and JNK,\textsuperscript{44} leading to AP-1 assembly on the \textit{MMP-1} promoter.\textsuperscript{30} 43 Consistently, PMA activates MAPK and AP-1 in AGS cells, and BIS I abolishes this effect. \textit{H. pylori} also induces MAPK, c-Jun and c-Fos, and activates AP-1 in AGS cells.\textsuperscript{35} 40 We found that BIS I suppresses c-Fos and c-Jun expression and AP-1 activity in infected cells. Surprisingly, BIS I had no effect on the phosphorylation of ERK or JNK, which mediate MMP-1 induction by \textit{H. pylori}.\textsuperscript{39} 46 These observations suggest that c-Jun and c-Fos regulation by PKC occurs apart from MAPK. In particular, the serum response factor (SRF) and members of the CREB/ATF family that control (together with Elk-1) c-Fos expression (figure 6F) are regulated by several Ca\textsuperscript{2+}-dependent kinases, including PKC.\textsuperscript{49} Further, depletion of PKC\textit{z}, PKC\textit{b} and PKC\textit{b} suppresses \textit{H. pylori}-induced c-Fos accumulation, and c-Fos depletion diminishes MMP-1 expression, indicating an important role of these PKC isoforms in c-Fos-dependent MMP-1 up-regulation. Indeed, in unaffected AGS cells, overexpression of active PKC\textit{z}, PKC\textit{b} and PKC\textit{b} increased the amount of c-Fos, AP-1 activity and invasion through collagen I-coated filters.

With respect to the mechanistic role of \textit{H. pylori} virulence factors, pronounced T4SS-dependent and T4SS-independent processes exist.\textsuperscript{48} Future work on the identification of the bacterial factor(s) responsible for PKC activation will give additional insights into the mechanisms of gastric mucosa colonization by \textit{H. pylori} and could provide a comprehensive picture of host–microbial interaction.

Acknowledgements We thank G Baier and S Shaw for the PKC expression constructs, U Lendeckel and S Krueger for the MMP-1 primers, S Kahler for the antibody to H\textsuperscript{+}, K\textsuperscript{ATPase}, and B Peters for help in ANOVA.

Contributors OS: experiments, analysis, interpretation of data and manuscript preparation; MV: biopsy collection, immunohistochemistry; MN: interpretation of data, manuscript preparation, and study supervision.

Funding The work was funded in part by the Deutsche Forschungsgemeinschaft (SFB 854) and the Bundesministerium für Bildung und Forschung (DFG/Systems, BMBF-0313922) by grants to MN.
