Mixed-lymphocyte reaction as a measure of immunological competence of lymphocytes from patients with Crohn's disease

ELIZABETH R. RICHENS, M. J. WILLIAMS, K. R. GOUGH, AND R. J. ANCILL

From the Pharmacology Department, University of Bath, and Department of Clinical Investigation, Royal United Hospital, Bath

SUMMARY Peripheral blood lymphocytes from 12 patients with Crohn's disease and from a group of normal volunteers have been tested for transformation under stimulation of allogeneic cells in a mixed lymphocyte culture and by phytohaemagglutinin (PHA) *in vitro*. There was a significant depression of transformation in the mixed lymphocyte culture where lymphocytes from the Crohn's disease patients constituted the responding population. With PHA stimulation, no difference in transformation was seen between the patients and the control group. This is interpreted as indicating a depression in cellular immunity in Crohn's disease.

A generalized depression of delayed hypersensitivity reactions has been noted in Crohn's disease. It is illustrated by such features as an impaired skin response to dinitrochlorobenzene (Jones, Housley, Ashurst, and Hawkins, 1969) and the tendency of Crohn's patients to be tuberculin negative (Williams, 1965). However, natural antigens elicit a normal response (Brown, Taub, Present, and Janowitz, 1970).

Further suggestions of anergy are given by the reduced transformation of lymphocytes *in vitro* under the stimulus of PHA (Walker and Greaves, 1969) and the failure to produce a macrophage inhibition factor in the presence of tissue antigens (Bendixen and Søberg, 1969).

In this communication, we report further investigations of immunocompetence of Crohn's patients using the technique of lymphocytic blastogenesis by stimulation with allogeneic cells in the mixed lymphocyte reaction and with PHA.

Materials and Methods

PATIENTS AND CONTROL SUBJECTS

Twelve patients with Crohn's disease, proven by radiological or histological evidence, were studied. Age, sex, duration of disease, and immunosuppressive treatment are shown in table II. Activity of

disease was judged on clinical criteria, including fever, weight loss, abdominal pain, and diarrhoea.

Twenty-one healthy controls were studied concurrently. For the PHA studies patients and controls were matched as far as possible for age and sex. HL-A phenotypes of the controls and patients were determined by the National Tissue Typing Reference Laboratory, Southmead. These data are listed in tables I and II.

PREPARATION OF CELLS

Cells for both tests were prepared from 50 ml freshly

Number	HL-A Phenotype

taken heparinized blood (20 iu preservative-free heparin per ml whole blood). The blood was layered over a mixture of Ficoll (6.5%) and Triosil (11.7%) and centrifuged at 1000*g* for 25 minutes at 20°C. The lymphocyte band was removed and washed in phosphate-buffered saline, pH 7.4, before being suspended in tissue culture medium (see below) to a concentration of 10⁶ cells per ml. Cells for mixed lymphocyte reactions were divided into two aliquots, one of which was given 4000r irradiation in a ⁶⁰Co source.

CULTURE CONDITIONS

Cells were cultured at 37°C in a humidified incubator in a medium consisting of TC 199 with Earle's salts buffered with 20 m M Hepes, supplemented with penicillin (100 U per ml), streptomycin (100 U per ml), 20% autologous plasma, and 2 mM L glutamine. Each cell suspension was made up in this medium before mixing for the mixed lymphocyte culture reaction.

For the mixed lymphocyte culture experiments 1 × 10⁶ lymphocytes in culture medium from the responding population were mixed with an equal number of lymphocytes from the irradiated stimulating population of allogeneic cells. The control consisted of responding cells mixed in equal numbers with stimulating cells from the same individual. In any series of experiments mixed lymphocyte cultures were performed using two control subjects and one Crohn's patient, each set of cells being used both as stimulators and responders with all cell types available.

Lymphocytes from each individual were also cultured in the presence of 1:20 PHA (PHA-m, Difco). This concentration was found to be optimal in experiments with two healthy subjects (table III). The control cultures for these cells consisted of irradiated cells cultured with PHA.

All determinations were made using triplicate cultures.

PHA Concentration	Subject A	Subject B
1:10	16.9	26.7
1:20	20.2	51.0
1:40	9.1	34.6
1:80	10.6	14.9
1:160	4.2	5.6

Table III Transformation indices obtained at varying concentrations of PHA in two healthy subjects

LABELLING AND HARVESTING CULTURES

Using predetermined kinetic data, a four-hour radioactive pulse was given on the third day for the PHA cultures and on the seventh day for mixed lymphocyte cultures. This consisted of 1.0 u Ci thymidine-(methyl-H3) (5.0 Ci/mmol, Amersham).

Cultures were terminated by cooling to 0°C and harvested onto glass fibre filter pads (GF/C, Whatman). Material remaining in the culture tube was washed onto the pad with 40 ml ice-cold saline and acid-insoluble material precipitated with 20 ml ice-cold 5% trichloroacetic acid. The filter pads were finally washed with 20 ml methanol, placed precipitate side up in scintillation vials, and dried at 120°C for four hours. Ten ml scintillation fluid (0.4% PPO, 0.005% POPOP in toluene) was added and the samples were counted in a Phillips scintillation counter, corrected for quench.

Results

The results for the mixed lymphocyte culture experiments were expressed in terms of a transformation index calculated as the ratio of radioactive thymidine incorporated in the allogeneic culture to its incorporation in a control culture consisting of the responding subjects' own cells as stimulators. Transformation indices obtained by this method are shown in figure 1.

The results for the PHA experiments were expressed as a transformation index calculated as the

Fig 1 Transformation indices obtained in the mixed lymphocyte reaction using lymphocytes from subject 1 as stimulating population and lymphocytes from various subjects as responding population.

ratio of radioactive thymidine incorporated in non-irradiated to irradiated cells.

Figure 2 summarizes the transformation indices obtained for mixed lymphocyte cultures using lymphocytes from patients and control subjects as both stimulating and responding populations. It shows the following features:

1 When both stimulating and responding cells came from the control group a range of transformation indices from 2.1 to 580.0 was obtained.

2 When the responding cells came from the Crohn's patient group and the stimulating cells from the control subject group the range of transformation indices was 2.1 to 33.8.

3 When the responding cells came from the control subject group and the stimulating cells from the Crohn's patient group the range of transformation indices was 2.1 to 310.0.

Using the Mann-Whitney two-sample ranking test, it is seen that in the group where Crohn's patient lymphocytes are the responding population the results are significantly different from both the other groups at the 5% level. This suggests a degree of anergy in the Crohn's patients.

The transformation indices were not found to

Mean TI = 11.4				Mean TI = 10.8			

Table IV Transformation indices (TI) obtained on stimulation of lymphocytes by PHA

correlate with either calculated or possible incompatibilities in HL-A phenotypic antigens.

Table IV shows the transformation indices for both the normal subjects and the Crohn's patients after stimulation by PHA. The two groups have the same mean transformation index and are not significantly different by either the Mann-Whitney U test or the t test. Hence by this method of stimulation the Crohn's patients show no difference in response from the normal subjects.

Table V summarizes the mean counts ($\pm$ SEM) obtained for each of the groups of patients and control subjects in both the mixed lymphocyte culture and PHA series of experiments. It will be seen that in the mixed lymphocyte culture the counts in the autologous control culture are similar for each group, the difference in transformation indices being due to the varying degrees of stimulation in allogeneic culture. In the PHA cultures, there is no significant difference in mean counts between patients and control subjects in either the irradiated or the non-irradiated cultures.

Discussion

The mixed lymphocyte culture test relies on the genetic disparity between two individuals, at or related to the HL-A locus, as expressed by the HL-A phenotypes on cell surfaces acting as antigenic stimuli in the induction of blastogenesis in each other's lymphocytes. The stimulation is two-way and one cell population is therefore prevented from transforming by prior irradiation. The measurement of thymidine uptake is thus confined to the responding population's lymphocytes.

Our results obtained by use of this test appear to suggest a depression of this function in the Crohn's group as compared to the normal subject. This supports the concept of a relative state of anergy in Crohn's disease suggested by previous work. (Jones *et al*, 1969; Williams, 1965; Brown *et al*, 1970; Walker and Greaves, 1969; Bendixen, 1969).

The anergy shown in Crohn's disease has suggested a link with sarcoidosis and many analogies have been

Mixed Lymphocyte Culture Reaction	Allogeneic Culture	Autologous Culture
Normal stimulators	47 392 $\pm$ 9079	2549 $\pm$ 593
Normal responders		
Normal stimulators	17 622 $\pm$ 6720	2141 $\pm$ 462
Crohn's responders		
Crohn's stimulators	85 926 $\pm$ 18 410	1980 $\pm$ 1620
Normal responders		
PHA Reaction	Non-irradiated Culture	Irradiated Culture
Normal subjects	38 898 $\pm$ 9320	3885 $\pm$ 901
Crohn's patients	41 208 $\pm$ 10 700	4524 $\pm$ 1220

Table V Mean Cpm ($\pm$ SEM) obtained from normal subjects and Crohn's patients on stimulation by mixed lymphocyte culture reaction and by PHA.

drawn between the two conditions (Brostoff and Walker, 1971). Recent work with the leucocyte migration inhibition test (Brostoff and Walker, 1971; Willoughby and Mitchell, 1971; Richens, Gough, and Williams, 1973) has shown that a high proportion of patients with Crohn's disease show altered migration patterns when incubated with sarcoid spleen suspensions.

In contrast with the results for mixed lymphocyte culture no evidence of impaired transformation was obtained with PHA stimulation. Considerable variation was seen on repeated tests with the same subject. This may reflect the activity of inhibitory factors in plasma (Holt, Ling, Winter, McCarthy, Read, and Yoffey, 1966). It is thought that PHA stimulation may not give a true reflection of immunocompetence (Han and Sokal, 1970), and that its mitogenic effect is concerned with its leucocyte agglutinating property (Hirschhorn, Kolodny, Hashem, and Bach, 1963). Although stimulation by PHA results in lymphocyte stimulation which is morphologically similar to that seen by other types of antigenic stimuli, it appears to be different in quantitative, qualitative, and biochemical respects.

The disparity seen between stimulation in the mixed lymphocyte culture reaction and by PHA may be explained on this basis, though the results with PHA are not in agreement with earlier work (Brown *et al*, 1970; Walker and Greaves, 1969).

No correlation was seen between transformation indices in either test and the taking of immunosuppressive drugs, though it is reported that prednisolone inhibits lymphocytic DNA synthesis induced by PHA (Caron, 1967).

In conclusion, the data for mixed lymphocyte culture provide additional support for the concept

of a degree of anergy in Crohn's disease. It is suggested that the failure to confirm this finding in the PHA experiments is due to the mode of action of this non-specific mitogen.

We are grateful for the advice of Dr S. Nelson and for the help of Mr C. Darke in carrying out the HL-A phenotyping.
