To investigate current practice in patient preparation prior to gastroscopy across the UK.

Methods A list of all Hospitals in the UK was obtained from the JAG website (391). Hospitals that did not perform endoscopy were excluded (14), as were Children's Hospitals (5) and private hospitals (165). The number of hospitals included was 207. A structured telephone survey was conducted with each endoscopy unit. The method of preparation prior to gastroscopy was established.

Results 193 (93%) endoscopy units responded to the survey. 11 (5%) endoscopy units declined to participate in the survey and 3 (2%) of endoscopy units did not respond. Preparation prior to gastroscopy (%) included:

1. 6 h nil by mouth (NBM) to food or clear fluids (38%)
2. 6 h NBM to food and NBM to clear fluids for 2 h (26%)
3. NBM to food and clear fluids from midnight for morning lists with 6 h NBM for afternoon lists (13%)
4. Nine different methods of preparation accounted for the remaining 23% of hospitals.

No hospital used a mucolytic drink for routine gastroscopy cases.

Conclusion Current gastroscopy preparation regimes vary across the UK. Future studies should evaluate which preparation regime provides the best possible visualisation of the upper gastrointestinal tract.

PTU-212 TO ANALYSE THE RISK OF STENT MIGRATION WITH THE NITI-S COVERED FLARED BILIARY STENT

doi:10.1136/gutjnl-2012-302514c.212

¹J K Moore,* ¹M Davies, ²M Sheridan. ¹Hepatology, St James University Hospital, Leeds, UK; ²Radiology, St James University Hospital, Leeds, UK

Introduction Stent migration occurs in 6%–12% of patients undergoing biliary stenting¹ The Niti-S fully covered metal stent (Taewoong Medical, Seoul) has a flared end which acts as anti-migration.² Few studies have evaluated the efficacy of these stents and are contradictory.^{3 4} The aim of our study is to compare their migration rates, investigate contributory factors and patient outcomes.

Methods This was a retrospective cohort study. 32 Niti-S flared stents were placed between January 2010 and July 2011. Each of the patients' records were analysed. The indication for stent, size and whether there had been any previous endoscopic therapy was recorded. The cholangiograms were then re-reviewed by an experienced radiologist to assess stricture length and position of the stent proximal to the stricture.

Results 10 out of 32 stents (31%) had migrated. Nine were placed for benign strictures and one for a malignant stricture. There was no significant difference between the stents that did and did not migrate comparing the length of stricture (mean 11.8 mm vs 12.4 mm), or where the stent was placed (mean proportion of stent above the proximal end of the stricture 16 mm vs 17.5 mm). There also appeared to be no association with previous endoscopic therapy: in 6 (60%) of the procedures where the stents had migrated there had been previous therapy, compared to 14 of the remaining 22 procedures (64%). 4 of the 9 (44%) patients with migrated stents were subsequently admitted to hospital with cholangitis, compared to 1 patient who did not have a migrated stent.

Conclusion The flared end covered metal stents significantly migrate despite the theories behind the design. Direct cost implications of this should be sought. There appears to be no association between aetiology, length of stricture, previous endoscopic therapy or where the stent was placed and subsequent migration.

PTU-213 SELF EXPANDABLE METAL STENTS (SEMS) FOR OBSTRUCTING COLORECTAL CANCER IN ENGLAND: LINKAGE ANALYSIS OF HOSPITAL EPISODE STATISTICS

doi:10.1136/gutjnl-2012-302514c.213

¹J Geraghty,* ¹S Sarkar, ²M Shawihi, ²E Thompson, ²M Pearson, ^{2,3}K Bodger. ¹Gastroenterology, Royal Liverpool University Hospital, Liverpool, UK; ²Aintree Health Outcomes Partnership, University of Liverpool, Liverpool, UK; ³Gastroenterology, University Hospital Aintree, Liverpool, UK

Introduction Colorectal cancer (CRC) is the 4th commonest cancer worldwide. Hospital admission with large bowel obstruction occurs in 15% and requires urgent decompression. SEMS can provide palliative treatment in advanced disease (avoiding surgical defunctioning) or preoperative bridging to elective surgery for operable disease. We aimed to describe a national profile for incidence (activity) of SEMS, volumes per Trust, length of stay and rates of readmission, reintervention and mortality for CRC in England.

Methods We developed techniques within the SPSS software package to identify a 1-year cohort of incident cases of CRC, starting with a merged file of raw HES data for all care episodes in English hospitals for 2006/7 and 2007/8. We selected only patients with first coding of CRC in the middle 12 months (October–September), then extracted all their admissions within 6 months (before and after) of first cancer coding, ordering them chronologically and then screening to identify admissions for SEMS and surgical procedures. Linkage to death registry provided date of death. Patients with SEMS and no subsequent surgical resection were flagged as palliative patients and those with a subsequent resection as bridge patients.

Results Overall: 517 patients were identified nationally as having SEMS placement for obstructing CRC (mean age: 72.6 yrs [SD: 12.0]; 62.5% male), with mean LOS of 7.9 [SD 11.3] days and overall mortality at 30 d (10.3%) and 90 d (18.0%). The 30 d emergency readmission rate was 15.1%. SEMS were code by 122 (81.3%) of acute Trusts in England, with volumes ranging from 1 to 24 per institution. **Palliative group:** (n=421, 81.4% of cases), mean LOS for index admission 9.2 [SD: 14.6] days and mortality at 30 d (12.1%) and 90 d (21.2%). Emergency readmission within 30 d (17.8%). Subsequent surgical colostomy coded in 9.5%. Palliative procedures were recorded in 122 Trusts (Volumes: 1–13 per institution), **Bridge group:** (n=96, 18.6% of cases), mean LOS for index admission 9.5 [SD: 10.4] days and mortality at 30 d (2.1%) and 90 d (4.2%). Emergency 30 d readmission (8.7%). Colostomy coded as part of surgery in 33.4%. Bridge procedures were coded in 48 (32%) acute Trusts (Volumes: 1–12).

Conclusion Analysis of HES data suggests SEMS insertion in English hospitals is predominantly for palliative purposes and most cases selected for this intervention survive beyond 30 days and avoid operative decompression. The use of SEMS as a bridge to surgery

was relatively uncommon and one third required a stoma at surgery. Variation between Trusts in coding quality is inevitable but the data suggest 1 in 5 institutions may lack provision for SEMS.

PTU-214 AN IN-VITRO STUDY TO ASSESS, AND IMPROVE, THE ACCURACY OF COLONIC POLYP SIZING AMONG NURSE ENDOSCOPISTS, TRAINEES AND CONSULTANT GASTROENTEROLOGISTS

doi:10.1136/gutjnl-2012-302514c.214

J Geraghty,* Z Raisi-Estabragh, M Gillon, P O'Toole, S Sarkar. *Gastroenterology, Royal Liverpool University Hospital, Liverpool, UK*

Introduction Knowing if polyps are larger than 10mm is critical when determining colonoscopic surveillance strategies. Judging polyp size from the endoscopic view alone becomes important if polyps are not retrieved intact. Strategies based on deliberately discarding small polyps rely on accurate discrimination of polyp size but little is known about endoscopists ability to make this judgement. Our aim is to assess the accuracy of polyp size estimation using a novel in vitro model, comparing different professional groups and use of accessories to improve estimates.

Methods Nine endoscopists (3 consultants, 3 trainees and 3 nurse endoscopists) judged the size of 15 "polyps" made from modelling clay (size range 6–36 mm) placed inside a colonoscopy training model (Koken Co Ltd, Tokyo). Polyps of different sizes were presented in random order. Size estimates were made using endoscopic visual assessment alone or by comparing the polyp to biopsy forceps or a 10 mm snare. A degree of confidence for each guess was recorded.

Results Consultants and trainees were significantly better than nurse endoscopists at judging whether the model polyps were larger or smaller than 10 mm (91.8% vs 79.2% $p<0.05$). Overall, visual assessment alone had an accuracy of 78.8%. Inaccuracy was largely due to underestimation of size. Use of accessories improved discrimination around the 10 mm threshold ($p<0.05$). The snare produced slightly better accuracy (87.9%) than forceps (83.8%) (NS). All professional groups expressed similar degrees of confidence in their estimates.

Conclusion In this model, medical endoscopists were better than nurse endoscopists in assessing the size of polyps. This may be because nurses in our study do not routinely perform polypectomy whereas doctors have all had the opportunity to learn from comparing the size of resected polyps with their original endoscopic assessment. Use of biopsy forceps or a snare improved size estimation and these may be helpful tools when teaching this important aspect of polyp assessment in vivo.

PTU-215 ASSESSING COMFORT SCORES FOR CO2 INSUFFLATION AS COMPARED TO AIR IN FLEXIBLE SIGMOIDOSCOPY-A PROSPECTIVE AUDIT

doi:10.1136/gutjnl-2012-302514c.215

J Tharakan,* D Beesley, A Kelling, R Radzioch, I Tiwari. *Endoscopy unit, Braintree Community hospital, Essex, UK*

Introduction Patients experience of discomfort with Air insufflation during flexible sigmoidoscopy (FS) limits compliance and thus

success of the procedure. There has been only one study¹ which has shown that CO2 insufflation reduces discomfort as compared to Air in FS. Recently, we have been using CO2 insufflation for routine FS. We therefore conducted a prospective audit comparing the two modalities and to assess whether the use of CO2 during FS reduces discomfort both during and after the procedure using a standardised scoring system.

Methods 200 consecutive patients undergoing FS, commonly for rectal bleeding, altered bowel habit and abdominal pain were selected to either Air or CO2 insufflation. There were 100 patients (42 males) in the CO2 group and 100 patients (51 males) in the Air group. The ages ranged from 19 to 92 years in both the groups. Any history of previous abdominal surgery was also noted. Patients were asked to grade discomfort during the procedure, post procedure in the recovery room and on discharge. We used the standardised comfort score of Wong and Baker (0=no discomfort and 10=extreme discomfort). Abdominal bloating was also assessed verbally after the procedure. Statistical analysis was done using Prism software.

Results The mean comfort scores for CO2 compared to Air during the procedure was 1.02 vs 1.93 ($p=0.0006$), postprocedure 0.54 vs 1.12 ($p=0.002$) and on discharge 0.32 vs 0.8 ($p=0.0008$) respectively. Abdominal bloating appeared to be less with CO2 as compared to Air on verbal questioning. No differences in comfort scores were observed with a history of previous abdominal surgery.

Conclusion This study has shown that CO2 insufflation reduces discomfort as compared to Air during FS, both during and after the procedure. Abdominal bloating was also significantly reduced. The use of CO2 will contribute to better public acceptance for FS, in particular for FS screening in colorectal cancer.

PTU-216 A SURVEY OF PATIENTS ATTITUDES TO COLONOSCOPY DEMONSTRATES HIGH VALUE FOR ENDOSCOPIST INTERACTION BUT NOT THE SINGLE SEX ENVIRONMENT

doi:10.1136/gutjnl-2012-302514c.216

J McEntire,* J Sahota, T Hyde, T Trebble. *Portsmouth Hospitals NHS, Portsmouth, UK*

Introduction Understanding patient attitudes to their medical experience is essential for optimising care and use of resources. This includes their interaction with their health practitioner and their healthcare environment. This study was undertaken to determine patient's preferences and expectations for outpatient colonoscopy, a common gastrointestinal procedure for which there is limited such data from the UK.

Methods Unselected patients attending for elective colonoscopy at a large District General Hospital on randomly selected days in October and November 2011 were invited to participate. Patients independently completed a composite, validated dedicated endoscopy questionnaire, with Likert scale anxiety-related and single sex environment questions and a 15-point preference (ranking) scale of aspects of endoscopy care that were considered most important (1) to least important (15) as contributing to a satisfactory experience. Qualitative and pilot studies were performed initially to confirm validity and reliability in the local population.

Results 217 out of 225 patients agreed to participate (96.4%); male (49%) and female (51%), with mean age of 58 years (range 16–87 years). Mild to moderate anxiety was recorded in over 70% of
