Results 136 patients were screened. There were 77 women and 59 men. The age range was 18–89 years. The mean age was 52.4 years. For women the mean age was 49.7 years. For men the mean age was 56.0 years.

There was a highly significant difference in the numbers referred to the dietitians. Using the NST scores, 3 out of 136 patients scored 12 or more (3 referrals (2%)). Using the MUST scores, 20 out of 136 patients scored 2 or more (20 referrals, (15%)) ($P < 0.0001$).

The NST identified that 12 patients scored 8 or more. 7 of these had a MUST score of 2 or more. This means 58% of patients who score 8 or more using the NST would have been referred using the MUST. The NST identified that 13 patients scored 7 or more. 8 of these had a MUST score of 2 or more. This means 62% of patients who score 7 or more using the NST would have been referred using the MUST.

The NST identified that 14 patients scored 6 or more. 9 of these had a MUST score of 2 or more. This means 64% of patients who score 6 or more using the NST would have been referred using the MUST.

Conclusion Using the NST results in a significantly lower number of referrals to dietitians compared to when nutritional assessment is made using the MUST score. This may be due to the NST score required for referral being too high. Therefore the NST needs to be revalidated using a lower referral score, possibly between 6 and 8. Further studies are required in order to ascertain the specific NST score appropriate for referral.

PTH-131 ENDOSCOPIC GASTROPEXY AND PEG FEEDING TUBE INSERTION: A COMPARATIVE STUDY

SS Salunke*, R McKay, D Barber, AW McKinlay, JS Leeds on behalf of PEG Research Group. *Gastroenterology, Aberdeen Royal Infirmary, Aberdeen, Aberdeen, UK*

10.1136/gutjnl-2014-307263.577

Introduction PEG feeding in patients with head and neck and upper GI cancers is known to derive nutritional and mortality benefits. Standard inside-out PEG insertion is not always technically possible or safe especially when there is narrowing of the oesophagus or pharynx from cancer. There is also concern about tumour seeding with inside-out technique. Similarly, in some patients it is not possible to pass the standard gastroscope through to upper GI tract. Gastropexy is an alternative technique which allows insertion of a gastrostomy tube with outside-in technique and can be performed using ultrathin scopes rather than standard gastroscopes. Gastropexy has been routinely performed in our unit for some time. We aimed to review the experience of Gastropexy insertion in our unit and compare it to age and indication matched controls who underwent PEG insertions.

Methods A retrospective review of institutionally approved PEG database was conducted. Gastropexy insertions between June 2009 and November 2012 and PEG insertions between March 2006 and January 2012 were reviewed retrospectively. Indication and age matched PEGs were used as controls. Patients with cancers (head and neck, oesophageal and other) undergoing the procedure were selected. Patient characteristics, sedation requirement, technical success, success using ultrathin scopes, safety, complications if any and mortality rates were recorded.

Results Fifty four patients received 57 gastroplexies (30 males, median age 63 (range 39–84) years); 108 patients received 109 PEG's (55 males, median age 68 (range 20–93) years).

Abstract PTH-131 Table 1

	Gastropexy	PEG	P value
Mean age (years)	63.2	66.9	0.08
Mean Midazolam (mg)	3.3	3.7	0.1
Mean Pethidine (mg)	25	0	<0.001
7-day mortality (%)	3.5	6.4	0.43
28-day mortality (%)	14	18.3	0.48
Indications	%	%	-
Head and neck cancers	68	67	-
Oesophageal cancers	21	6.4	-
Cancers elsewhere/extrinsic compression	2	26.6	-

Eighty three percent of gastropexy and 97% of PEG's were done under conscious sedation. The remaining gastropexy insertions were done under GA as a part of another surgical procedure. Technical success was achieved in 98 and 100% for gastropexy and PEG's respectively. Minor gastric fluid leak in 1 patient in gastropexy group and mouth bleed in 1 patient in PEG group was noted. No procedure related deaths were noted in either of the groups.

Conclusion In the context of risk from tumour seeding and mucosal trauma to narrowed upper GI tract, endoscopic gastropexy procedure seems non-inferior to PEG's. It seems safe and can be done with high technical success rate. Perhaps, it may be an alternative to PEG in patients with inherently difficult upper GI tract and major illness like cancers.

PTH-132 GASTROSTOMY INSERTIONS: IS IT ALL ABOUT CHOOSING THE RIGHT PATIENTS? A COMPARISON BETWEEN PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) AND RADIOLOGICALLY INSERTED GASTROSTOMY (RIG) INDICATIONS, COMPLICATIONS AND MORTALITY RATES

T Abd Rahim*, C Sharratt, M Tinker, T Buchanan, T Bowling. *Nottingham University Hospitals (NUH) NHS Trust, Nottingham, UK*

10.1136/gutjnl-2014-307263.578

Introduction Nottingham University Hospitals (NUH) NHS Trust serves as a tertiary centre for Gastroenterology, Stroke, Neurosurgery and Oncology. Our current practice for vetting referrals differs for PEG and RIG. PEG requests are forwarded to the Nutrition Team for vetting. RIG referrals are sent directly to Radiology for vetting. Our Specialist Nutrition nurses provide a robust assessment including clinical assessment, dietitian and speech and language therapy review. Complex cases are discussed with a Gastroenterologist. Pre-procedure review of RIG patients may be undertaken by any physician.

Methods We retrospectively reviewed all PEG and RIG referrals from 2012. The nutrition records, case notes and electronic records were reviewed. We collected data on referring specialty, indication and 30-day complication and mortality rates. Data was collated onto a database for analysis.

Results 329 referrals were received; 148 for PEG and 181 for RIG. Of these, 76 (51.4%) were deemed appropriate for PEG and 168 (92.8%) for RIG. Reasons for refusal included patient fitness, meeting nutritional needs, suitable for alternative method of feeding or unsuitable for anatomical/technical reasons. Main service users were Stroke and Neurology, other medical specialties, Clinical Oncology, Neurosurgery and Ear, Nose and Throat.

Indications included intracranial events, head and neck cancers and dysphagia secondary to gastroenterological, neuromuscular or neurodegenerative conditions.

30-day complications: Stoma site infections; (15.8% for PEG and 19.6% for RIG), chest infections; (6.58% for PEG and 6.55% for RIG) and minor complications (including blocked or dislodged tube); (5.26% for PEG and 11.9% for RIG). Major complications were low (0% for PEG and 2.97% RIG - including perforation (0.60%), respiratory arrest (0.60%), desaturation (0.60%) and pneumoperitoneum (1.19%)). 30-day all-cause mortality was 6.58% (PEG) and 8.33% (RIG).

Conclusion Pre-screening PEG referrals identified more inappropriate cases than those referred for RIG. With the exception of chest infections, 30 day minor and major complications were lower in the PEG group, as was 30-day all-cause mortality. We hypothesise that the less rigorous screening process may be contributing to excess complication and mortality rates of RIG insertion. This may, or may not be unique to our Trust. RIG is usually the second line method of insertion, and we recognise that this patient group may have a poorer premorbid state. We recommend formal assessment of all gastrostomy referrals regardless of insertion technique. The Nutrition Team is currently looking towards pre-screening all gastrostomy referrals.

PTH-133 ELECTRONIC PERSONAL HEALTH RECORDS FOR PATIENTS ON HOME PARENTERAL NUTRITION: A PATIENT SATISFACTION SURVEY

¹T Ambrose*, ²R Topan, ¹M Small, ¹JM Nightingale, ¹SM Gabe. ¹Lennard Jones Intestinal Failure Unit, St Mark's Hospital, London, UK; ²Northwick Park Hospital, London, UK

10.1136/gutjnl-2014-307263.579

Introduction The public demand for flexible access to health information and services is growing, encouraged by Internet trends and policies promoting patient involvement. Patients Know Best® (PKB) is an electronic patient centred system providing a secure forum for patients to interact with healthcare teams. With increasing use of this system by our home parenteral nutrition patients we aimed to assess patient satisfaction with a survey.

Methods PKB was introduced to patients during routine clinic visits and verbal consent obtained. We recorded the frequency of use, total number of electronic discussions held and the number of additional carers (other healthcare staff or family members) involved in their personal health record. We distributed a 10 question survey to all users.

Results 119 patients (50 male, 69 female) were registered over a period of 18 months with a median age of 49 years (range 17–85 years, mean 48 years). A total of 5015 unique electronic conversations were recorded. These would usually have occurred via telephone. PKB has been used for 4 patients transitioning from paediatric to adult services and 2 patients from abroad. Other patients invited included 128 outside clinicians (eg local nutrition nurses and dietitians, transplant coordinators) and 29 carers. There were 58/119 (48.7%) responses including 1 incomplete dataset (61% female). 31/57 patients (54.4%) were over 50 years of age. 42/57 (73.7%) received parenteral nutrition and 13/57 (22.8%) fluids and electrolytes. 51/58 (87.9%) patients felt at least “somewhat confident” working online with their healthcare team and the same number felt that having access to the results was at least “somewhat helpful” – 32 (62.7%) of these responding “very/extremely helpful”. 30/58 (51.7%) use PKB a few

times a month, 4/58 (6.9%) a few times a week and the remainder less frequently. The more useful features of PKB included Discussions (ie contacting the St Mark's Nutrition team electronically) and Monitoring (ie test results). Patients use PKB to contact doctors/nutrition nurses more than dietitians/administrators.

Conclusion Our survey suggests that our patient cohort find this a useful facility to contact us and improve the management of their long-term conditions. Not all patients access PKB regularly and they only had a short period in which to respond to the survey. This may explain the 49% response rate in an otherwise motivated patient population. This is an emerging and effective way for patients to interact with their healthcare teams and we have not found it has increased our workload. The ability to communicate seamlessly between different healthcare professionals reduces the current difficulties which exist when transferring information between multiple care providers (eg HIFNET).

PTH-134 MALNUTRITION SCREENING IN HOSPITAL OUTPATIENTS

¹Z Gundkalli, ²V Blackwell, ²W Howson*, ²H Williams. ¹Imperial College School of Medicine, London, UK; ²Imperial College Healthcare NHS Trust, London, UK

10.1136/gutjnl-2014-307263.580

Introduction NICE Guidelines (2006) advocate the screening of all new hospital outpatients in order to identify individuals at risk of malnutrition within the community. However, existing data in support of outpatient screening are limited. To establish the utility of screening in specific outpatient settings, data were collected from targeted clinics. Patterns of risk associated with age, gender, ethnicity and ‘new’ or ‘follow up’ outpatient status were determined.

Methods The Malnutrition Universal Screening Tool (MUST) was used to assess the nutritional status of all individuals attending outpatient appointments at eight clinics at St. Mary's Hospital, Imperial College Healthcare NHS Trust. These were Gastroenterology, General Surgery, Geriatric Falls, Oncology, Chest and Allergy, Hypertension, Dermatology and Gynaecology/Urogynaecology. Appropriate action was taken as per guidelines for patients identified as ‘at-risk’.

Data were analysed using descriptive statistics, chi-square and logistic regression.

Results 585 outpatients were screened over a six week period (male 35.9%, n = 210/585; female 64.3%, n = 375/585; median age = 52, range 16–91 years; white ethnicity 57.7%, n = 338/585; non-white ethnicity 42.3%, n = 247/585). The overall prevalence of malnutrition risk was 12.1% (n = 71/585). There was a significantly higher risk of malnutrition in the young (16–24 years) and the elderly (≥ 75 years) (p = 0.04) and in individuals of white ethnicity (p = 0.0002). There was no difference in the prevalence of risk between new or follow up patients.

There was a predictably high yield in Gastroenterology, General Surgery, Oncology and Geriatric Falls clinics. Low prevalence of risk was found in Hypertension and Gynaecology/Urogynaecology clinics.

The Dermatology clinic yielded notable results with a 15.0% (n = 12/80) prevalence of risk. 8/12 of these patients were identified as medium risk (MUST score 1) due to a BMI of 18.5–20.0 kg/m²; 7/8 were female and of white ethnicity.

Conclusion There have been no published studies of larger cohorts in a hospital outpatient setting.
