SUMMARY The effects of drugs which change the bile-salt-independent fraction of bile flow on Na\(^+\)K\(^+\) and Mg\(^2+\) activated ATPases were studied in membrane fractions rich in bile canaliculi.

The administration of phenobarbital caused no induction of these enzymes which could explain the increased bile flow observed in the rat.

Rose bengal, in addition to its strong photooxidative inhibition of both ATPases, inhibits the Na\(^+\)K\(^+\) ATPase of rat and rabbit bile canaliculi in the absence of light. A closely related substance, uranine, inhibits neither bile flow nor Na\(^+\)K\(^+\)ATPase. Inhibition of this enzyme by rose bengal may therefore be responsible for the observed effects of this dye on bile flow independent of bile salts.

Phenobarbital increases the bile flow of the rat (Hart, Guarino, and Adamson, 1969; Klaasen, 1969; Roberts and Plaa, 1967; Robinson, 1969a and b; Berthelot, Erlinger, Dhumeaux, and Preaux, 1970); rose bengal lowers this flow in the rabbit (Dhumeaux, Erlinger, Benhamou, and Fauvert, 1970). Both actions seem to be due to alterations in the recently described bile salt-independent fraction of bile secretion (Berthelot et al, 1970; Dhumeaux et al, 1970). We attempted to investigate whether these effects were operated through changes in ATPase activities in plasma membranes of the hepatocytes.

Material and Methods

HEPATIC PLASMA MEMBRANES OF RATS TREATED WITH PHENOBARBITAL

Administration of phenobarbital
Male Charles River rats weighing 180-200 g were separated into two groups. One received daily injections of sodium phenobarbital, dissolved in isotonic saline (16 mg/ml; 8 mg/100 g of body weight) for 10 days. The control group had a daily injection of isotonic saline.

Preparation of plasma membranes
At least 18 hours after the last injection the rats were stunned (two rats for each preparation); their livers were perfused with cold 1 mM NaHCO\(_3\), then homogenized in a glass-teflon potter using 10 ml of the same solution for each gram of liver and diluted three times. Membranes were prepared according to the technique of Pfleger, Anderson, and Snyder (1968) slightly modified and adapted to a Spinco BIV zonal rotor.

The membrane fraction appeared on the 280 m\(\mu\) absorption curve of the final effluent as a slightly asymmetrical peak (density from 1.17 to 1.20) (Fig. 1). This fraction was diluted with half a volume of 1 mM NaHCO\(_3\), and centrifuged in a SW 25-1 rotor at 66 000 g for 10 minutes. The pellet was homogenized again in 30 ml of bicarbonate solution and centrifuged for 10 minutes at 600 g to discard mitochondria and smaller membrane fragments. The resulting pellet, homogenized once again in 5 ml distilled water, was used for enzyme assays. The whole process took six hours. Some of the preparations were examined under the electron microscope.

Chemical determinations
The following assays were performed as soon as the final membrane suspension was obtained: protein (Lowry, Rosebrough, Farr, and Randall, 1951), succinodehydrogenase (SDH) (Pennington, 1961), glucose-6-phosphatase (G-6-Pase) (Swanson, 1955), 5-nucleotidase (5'AMPase) (Heppel and Hilmoe, 1955). The ATPases were assayed using a slight

Results

MEMBRANE FRACTIONS

The electron microscope showed that membrane fractions were mainly composed of bile canaliculi (Figs. 2 and 3). Concentrations of marker enzymes in the rat membrane fractions were comparable to those observed by other authors (Emmelot and Bos, 1966; Coleman, Michell, Finean, and Hawthorne, 1967; Weaver and Boyle, 1969; Hinton, Dobrota, Fitzsimons, and Reid, 1970) as far as Mg²⁺-activated ATPase (94 ± 37.5), Na⁺K⁺ ATPase (17.3 ± 7.5), and 5 nucleotidase (46.6 ± 17.6) were concerned. Mitochondrial (SDH = 1.08 ± 0.97) and microsomal contaminants (G-6-Pase = 5.8 ± 3.3) were somewhat higher.

A study of marker enzymes of plasma membranes has not previously been published for the rabbit. ATPase activity was similar to that of rat plasma membranes (Mg²⁺-activated ATPase: 66 ± 38; Na⁺K⁺ATPase 11 ± 6); 5-nucleotidase was very low (6.7 ± 2.6) but no AMPase could be demonstrated in rabbit plasma membranes by histochemical methods (Wachstein, 1963). Mitochondrial and microsomal contaminants were low (SDH: 0.38 ± 0.22; G-6-Pase: 1.33 ± 0.99).

EFFECTS OF PHENOBARBITAL ADMINISTRATION

For treated rats there was a 25% increase in the relative weight of the liver (Table I). The 5-nucleotidase activity of whole liver homogenates was 40% lower in treated animals when expressed as specific activity and 22.5% lower when referred to body weight (Table I). In plasma membranes specific activities of 5-nucleotidase, G-6-Pase, and SDH were not significantly altered (Table II). Mg²⁺

modification of the method described by Wheeler and Whittam (1962). Na⁺K⁺ ATPase activity was defined as the difference between the activities measured without ouabain in the incubation medium (total ATPase) and with the inhibitor (Mg²⁺ activated ATPase). The same results had been obtained in pilot experiments when Tris-ATP, prepared according to Järnefelt (1961), was used with and without Na⁺ according to Emmelot and Bos (1966). Enzyme activities were also assayed in whole liver homogenates. All activities were expressed as moles of substrate/hr/mg protein. Means were calculated ± SD and results were compared using Student’s t test.

EFFECTS OF ROSE BENGAL AND URANINE ON ATPASE ACTIVITIES OF LIVER PLASMA MEMBRANES IN THE RAT AND THE RABBIT

Membranes were prepared as indicated above from normal male Charles River rats. The effects of different concentrations of rose bengal and uranine (from 0.13 to 17 nmole/ml incubation medium) upon 5 nucleotidase, Mg²⁺ activated ATPase, and Na⁺K⁺ ATPase activities were studied. Sodium activation was used instead of ouabain inhibition to distinguish between the different ATPase activities, since interference between rose bengal and ouabain was observed. When rose bengal was used assays were performed in daylight and in the dark. In the latter situation minimal exposure to red light was used for adding rose bengal, substrate, and, 10 minutes later, trichloracetic acid to the incubation medium. The effect of uranine was assayed only in the dark, using yellow light during pipetting.

The same preparation procedures and enzymatic assays were carried out for rabbit liver.

All results were expressed as indicated above.
Fig. 2  Plasma membrane fraction from rat liver (× 18000): it is mainly composed of the bile canaliculi closed by desmosomes (—) or occasionally ruptured (—). Microvilli are numerous; some are swollen, others still seem to contain some cytosol.

Fig. 3  Plasma membranes from rabbit liver (× 11000). The same structures are observed as in the rat.

**Effects of Rose Bengal and Ura nine on Plasma Membranes in Rat and Rabbit Liver**

In the rat rose bengal had no effect on 5-nucleotidase. In daylight (Fig. 4) it inhibited Mg$^{2+}$ activated ATPase (50% inhibition with 2.5 nmoles/ml); Na$^+$K$^+$ ATPase was much more sensitive (50% inhibition with 0.3 nmoles/ml). In the dark (Fig. 4)

**Discussion**

A correlation between Na\(^{+}\)K\(^{+}\) ATPase and the bile-salt-independent fraction of bile secretion has been suggested since this fraction is inhibited by ouabain and ethacrylic acid in the rabbit (Erlinger, Dhumeaux, and Benhamou, 1969; Erlinger, Dhumeaux, Berthelot, and Dumont, 1970). In this species rose bengal has also been shown to inhibit the bile-salt-independent fraction in the secretion of bile by an unknown mechanism (Dhumeaux et al, 1970). Rose bengal inhibition of the Na\(^{+}\)K\(^{+}\) ATPase of red cells in daylight has been shown to be responsible for the haemolytic action of this dye (Duncan and Bowler, 1969). In daylight rose bengal inhibits both ATPases in membrane fractions composed mainly of bile canaliculi. However such photo-dependent inhibition cannot occur in the abdominal cavity. The inhibition of red cell Na\(^{+}\)K\(^{+}\) ATPase in the dark is a controversial matter (Blaiklock and Green, 1971; Borgese and Green, 1962). Liver plasma membrane Na\(^{+}\)K\(^{+}\) ATPase activity is inhibited in the dark by concentrations 1000 times lower than those produced in rabbit bile by an intravenous injection of rose bengal which lowers the bile flow, that is 6 mg/ml (Dhumeaux, personal communication). Uranine, which does not lower bile flow (Dhumeaux et al, 1970), in spite of its chemical resemblance to rose bengal (disodium fluorescein versus disodium tetrachlorotetraiodofluorescein), has no effect on either ATPase activity in vitro. The inhibitory action of rose bengal on the bile-salt-independent fraction in the bile secretion of the rabbit may therefore have the same mechanism as that of ouabain and ethacrylic acid, which would be consistent with the concept attributing the secretion of this fraction in rabbit liver to the activity of Na\(^{+}\)K\(^{+}\) ATPase.

In the rat the problem is more confused. According to a brief preliminary report (Berthelot, 1971), ouabain and ethacrylic acid do not inhibit in vivo the bile-salt-independent fraction of bile secretion in the rat; the low sensitivity of the rat to cardiac glycosides was considered to be a possible reason for this. Recently inhibition of the bile-salt-independent
fraction in bile flow by extremely high concentrations of scillaren has been described in the isolated perfused rat liver (Boyer, 1971). If the mechanism of this secretion is similar to that of the rabbit, rose bengal should also inhibit secretion of this fraction in the rat since in vitro the dye has much the same effect in both species. This inhibition is being studied.

Induction of Na⁺K⁺ ATPase by phenobarbital in rat bile canaliculi would have been expected to yield some further evidence on the role of this enzyme in bile flow. The present results show no such induction. In the membrane fraction, the ratio of both ATPases activities to the 5-nucleotidase activity is unaffected by phenobarbital. The latter enzyme activity is significantly decreased when referred to liver weight. This decrease is still present although to a lesser extent when 5-nucleotidase activity is referred to body weight and cannot therefore result from a mere dilution of plasma membranes by the increase of microsomal protein, which itself lowers the specific activity of 5-nucleotidase in the whole homogenate. The mechanism for the increase in bile production by phenobarbital therefore remains unknown. It should be noted, however, that this increase has the same order of magnitude as the increase in liver weight (Berthelot et al., 1970) although other work has shown that all microsome inducers do not share this property in spite of the enlargement that they provoke in the liver (Klaasen, 1969).

Y. Laperche is Stagiaire de Recherche and Mme A. Launay Attachée de Recherche in the Institut National de la Santé et de la Recherche Médicale (INSERM).

We wish to thank Mrs M. C. Oueda for the electron microscopic examination of the membrane preparations, P. Berthelot and S. Erlinger for fruitful discussion, and Miss M. H. d'Assumcao for her help in preparing the manuscript.
