Painful rib syndrome

EDITOR,—The painful rib syndrome recently described by Scott and Scott is, in my opinion, a misnomer. Over the years I have seen numerous cases similar to the ones they report, and have found that the tender spots they allude to are not in the ribs but in the muscles. They are, in fact, myofascial trigger points. Pain develops because of trauma induced activation of nociceptors at these sites in what is now called the myofascial pain syndrome.1 These trigger points may be found in any muscle in the body. In the abdomen they commonly occur in the rectus abdominis and external oblique muscles. They do not only develop, however, at or near to their insertion into the ribs, but also in their bellies and at lower attachment sites such as the iliac crest, inguinal ligament, and pubic bones.

The pain emanating from trigger points in this syndrome may be abolished by injecting a local anesthetic into them.2 Recently it has been shown that pain is also relieved by stimulating A-delta nerve fibres at these sites with dry needles; treatment that is physiologically more rational being simpler, safer, and equally effective.1

Gastroenterologists must learn to recognise 'trigger point pain' because it is common and can be treated. The concept of the painful rib syndrome restricts the diagnosis to pain in the lower thorax and upper abdomen, as well as implying that there is no effective treatment other than reassurance. Trigger point pain may occur anywhere in the abdomen with additional sites in the perineum and back. The pain can be recognised easily so unnecessary investigations and operations are avoided. It usually responds quickly to acupuncture; further courses can be given if relapse occurs.

Colonicoscopy surveillance in ulcerative colitis

EDITOR,—We read with interest the article by Lynch et al (Gut 1993; 34; 1075–80), and agree that the problem of defining those patients at risk of developing colorectal cancer poses great logistical problems. Yearly surveillance colonoscopy did not detect most of the cancers in patients with colitis, but this was because nearly all patients in whom cancer eventually occurred fell outside their surveillance programme. Only three of nine patients who developed colonic cancer had their disease initially assessed by colonoscopy, and a further two patients had total colitis diagnosed by barium enema. We would suggest that ideally all patients with an initial diagnosis of colitis should have the extent of their disease assessed colonoscopically, thereby better defining those patients deemed to be at higher risk of developing cancer.

It is obviously true that colonoscopy will not prevent cancer from developing in the colitic colon because of the imperfect link between dysplasia and cancer, and because of the low proportion of the surface area of the colon biopsied during surveillance colonoscopy. We would therefore propose that surveillance colonoscopy should not be the only follow up for those patients at a risk of colorectal malignancy.
