Epidemiology supports oral contraceptives as a risk factor in Crohn’s disease

EDITOR,—A recent clinical alert (Gut 1999;44:311–12) commented on a study of risk factors for relapse in Crohn’s disease.1 The author concluded that, unlike the established association with smoking, the link with oral contraceptive use is still controversial. To contribute to this discussion, I have investigated temporal trends in age and sex specific disease incidence and correlated them with the chronology of oral contraceptive use.

The birth control pill was first introduced in 1960 and soon became widely accepted; 10 million American women were taking it by 1973.1 Concerns about side effects prompted further research, and by the mid-1970s most women taking were taking oral contraceptive pills containing 50 µg or less of oestrogen—a considerable decrease from the 100–150 µg in the pills of the 1960s.

Most epidemiological studies of Crohn’s disease (especially those from the USA) have shown a rapid rise in the incidence of disease between the early 1960s and early 1970s, followed by a plateau phase in the 1980s.2 In my analysis I have used the only two American studies3 for which detailed age and sex incidence distributions were available and correlated them to American data on oral contraceptive use. Without investigating the incidence trends in a group of 20–29 year old women (those who were the most likely users of oral contraceptives), a correlation between the introduction and adoption of oral contraceptives and overall incidence trends of Crohn’s disease would not be sufficient to establish oral contraceptive use as a risk factor. From 1964, both studies showed that there was a striking increase in incidence among the 20–29 year old group, and an increased female to male incidence ratio. Unpublished data from the Olmsted County study4 showed a crude incidence of 28.8 cases per 100 000 person years for this age group in women between 1964 and 1973. This is the highest incidence among all age and sex groups in the entire study period (1940–93), and the highest incidence rise between consecutive time periods. The incidence rise in men for the same period was much less dramatic and the crude rate for the same age group was 17.2. Data for Baltimore showed a 4.46-fold increase in incidence for women aged 20–29 between the 1960–3 and 1973 surveys, and only a 2.33 increase for men of the same age group. Again, this jump in female incidence is the most abrupt and other highest incidence among all age and sex groups in all periods. Consistent with the introduction of oral contraceptives with a lower oestrogen content, incidence studies of Crohn’s disease reported lessening of predominance in women aged 20–29 from the mid-1970s. Figure 1 shows changing female to male incidence ratio for this age group corresponding to oral contraceptive use.

Although detailed data on incidence and oral contraceptive use were not available, we used two European studies as controls,5 and, in the period 1960–5, both had the highest female to male incidence ratio, which corresponded to the rise in the USA.

The above epidemiological findings are concordant with Timmer and colleagues’ study and support their explanation that previous use of oral contraceptives is more strongly associated with relapse in Crohn’s disease than current use. The change in oestrogen content of oral contraceptives may account for the contradictory findings of a link between oral contraceptive use and Crohn’s disease, in studies published in the past 15 years.

The author would like to thank Edward V Loftus Jr for contributing unpublished data from the Olmsted County study.

The role of psychological and biological factors in postinfective gut dysfunction

EDITOR,—We read with interest the paper by Gwee et al (Gut 1999;44:400–6) which described the role of psychological and biological factors in postinfective irritable bowel syndrome (IBS). However, these authors did not study fructose or lactose malabsorption in relation to duodenal function. Carbohydrate malabsorption syndromes—

Reply

EDITOR,—I would like to thank Dr Ledochowski and colleagues for their interest in our paper, and for presenting evidence of a possible association between fructose or lactose malabsorption and mental depression. They suggest that psychological symptoms in patients with IBS may be due to carbohydrate malabsorption, caused by the interaction between malabsorbed sugars and the amino acid tryptophan. In contrast, we proposed that psychopathology predisposes to the development of IBS. We observed that neurotic traits, life events occurring before an attack of gastroenteritis, and psychological state at the time of the infection, all seemed to predict which patients would develop IBS.

I would not deny that events in the gut may influence state of mind. Research from our department, and others, has indicated that meals rich in fat induce feelings of calmness,
Is isolated idiopathic pancreatitis associated with CFTR mutations?

Editor.—In one of two recently published studies which looked at a link between mutations of the cystic fibrosis transmembrane conductance regulator (CFTR) gene and idiopathic pancreatitis, 1 Cohn *et al* estimated that 37% of a cohort of 27 patients with idiopathic pancreatitis had at least one abnormal CFTR gene, which is 11 times the expected frequency. 1 Furthermore, the authors concluded that additional CFTR mutations might be detected by more comprehensive DNA testing, because they had tested DNA samples for only 16 of the more than 800 mutations associated with cystic fibrosis.

| Table 1 Characteristics of 10 patients with idiopathic pancreatitis |
|-----------------|-----------------|-----------------|-----------------|-----------------|
| Patient no. | Sex | Current age (y) | Age at diagnosis (y) | Sequence changes |
| 1 | M | 77 | 75 | IVS8 T/Gn-Tn 1540 A/G |
| 2 | 52 | 41 | 3041-71A/G |
| 3 | M | 44 | 42 | 4002A/G |
| 4 | F | 70 | 69 | 875+40A/G |
| 5 | M | 62 | 61 | 125G/C |
| 6 | F | 52 | 50 | 1716GA |
| 7 | M | 41 | 38 | 125G/C |
| 8 | M | 64 | 36 | 1505V |
| 9 | M | 72 | 69 | 875+40A/G |
| 10 | F | 18 | NA | 1540 A/G |

In order to document further whether a proportion of adults presenting with idiopathic pancreatitis carry alleles linked to mild abnormalities of CFTR functions, we conducted a complete scan of CFTR sequences by denaturing gradient gel electrophoresis (27 exons) and other appropriate methods (four intronic regions), in a sample of 10 patients with isolated idiopathic pancreatitis (ascertained by standard criteria) in the south of France. As some CFTR alleles that have been linked with specific DNA marker haplotypes have recently been shown to produce incomplete or less functional CFTR protein, 2 we also thoroughly studied the T/Gn-Tn loci in the branch/acceptor splice site in intron 8 and the 1540 A/G locus (named M470V) in exon 10. Exclusion criteria included the ingestion of more than two alcoholic drinks per day (20 g ethanol), cancer, drug or trauma related pancreatitis, and familial chronic pancreatitis. None of the patients had any clinical manifestation or family history suggestive of cystic fibrosis or CFTR associated diseases. The study was approved by our ethics committee.

We thank Ms Freies for contributing clinical data and Ms Seguret for statistical advice. This research was supported by the Direction de la Recherche Clinique, CHU, Montpellier, France (UF733).

Did prostaglandin E stimulates glucose absorption in rat intestine?

Editor.—I read with interest the recent paper by Schotka *et al* (Gut 1999;44:490-496) which reported that prostaglandin E, (PGE), stimulated glucose absorption via the sodium dependent glucose transporter-I in rat intestine.

The authors suggested that PGE, raises sodium dependent glucose transporter (SGLT1) and thus increases glucose absorption. However, earlier papers contradicted this theory and we are now in a state of confusion. Kimberg and coworkers 1 and Klæve-

| Was isolated idiopathic pancreatitis linked to mild abnormalities of CFTR functions, we conducted a complete scan of CFTR sequences by denaturing gradient gel electrophoresis (27 exons) and other appropriate methods (four intronic regions), in a sample of 10 patients with isolated idiopathic pancreatitis (ascertained by standard criteria) in the south of France. As some CFTR alleles that have been linked with specific DNA marker haplotypes have recently been shown to produce incomplete or less functional CFTR protein, 2 we also thoroughly studied the T/Gn-Tn loci in the branch/acceptor splice site in intron 8 and the 1540 A/G locus (named M470V) in exon 10. Exclusion criteria included the ingestion of more than two alcoholic drinks per day (20 g ethanol), cancer, drug or trauma related pancreatitis, and familial chronic pancreatitis. None of the patients had any clinical manifestation or family history suggestive of cystic fibrosis or CFTR associated diseases. The study was approved by our ethics committee.

Table 1 summarises the CFTR genotypes identified in the 10 patients with idiopathic pancreatitis. Of these, no patient had a cystic fibrosis mutation and seven were instead heterozygous for one or two sequence changes that have been classified as DNA sequence polymorphisms/variants (a complete list of these variations can be found on the cystic fibrosis mutation database: www.genet.sickkids.on.ca/cftr).

In conclusion, extensive analysis of CFTR sequences in a subset of patients from the south of France does not confirm a link between CFTR alterations and isolated idiopathic pancreatitis.

Although variant 1716G/A (no change at glutamine 528) may result in exon 10 skipping and has been reported in CFTR related diseases, 1 the involvement of this variant in cystic fibrosis remains controversial. The frequency of the IVS8-5T allele (10%) was 2.3 times the observed frequency in the general population (4.3%). It is unlikely, however, that this allele is a variant which predisposes towards idiopathic pancreatitis because it is carried on a TG11-7AG, and one cystic fibrosis mutation (AF508) were observed. In conclusion, extensive analysis of CFTR sequences in a subset of patients from the south of France does not confirm a link between CFTR alterations and isolated idiopathic pancreatitis.

We thank Ms Freies for contributing clinical data and Ms Seguret for statistical advice. This research was supported by the Direction de la Recherche Clinique, CHU, Montpellier, France (UF733).

prostaglandin may inhibit SGLT1 activity. Furthermore, a decrease in active absorption of glucose due to increased levels of prostaglandins and cytokines has been observed both in patients with severe intestinal inflammation and surgical patients.¹ Can other mechanisms explain an alternative mechanism for their findings?

Reply
Editor.—We see no reason for confusion over the acute increase of PGE₂-stimulated glucose absorption via SGLT1 with cAMP, raised by cyclic 3',5'-AMP inhibited Na⁺-ATPase activity in plasma membrane preparations of rabbit jejunum decreased three hours after cholea toxin treatment; they did not study the direct acute effect of cAMP or PGE₂, Sundaram and colleagues, using a rabbit model of chronic ileal inflammation (cells isolated 13–15 days after intragastric inoculation with Eimeria magna oocytes), concluded that Na⁺-glucose cotransport reduction was secondary to a decrease in the amount of SGLT1; PGE₂ involvement in this chronic alteration was not examined.

Somasundaram et al, who used a rat model of extraintestinal inflammation (six hours after formalin injection into hind leg pad), showed that glucose absorption was impaired in the jejunum, and that this impairment could be prevented by the anti-inflammatory drug, oxypHENbutazone; again PGE₂ involvement was not investigated. Ohri and colleagues reported that monosaccharides were malabsorbed in coroNary artery bypass pa-tients, because of significant hyperperfusion of the intestine; they did not study the involvement of PGE₂. Finally, Wicks et al concluded that enteral feeding was as effective as total parenteral nutrition in orthotopic liver trans-plantation; they also did not examine the involvement of PGE₂.

In summary, Dr Somasundaram has not presented any evidence that PGE₂, lowers SGLT1, activity and acutely or chronically decreases glucose absorption. There is no discrepancy between our findings and any previous study. As PGE₂, or any similar hormone or mediator, may have different short term acute and long term chronic actions, and because an appropriate distinction has yet to be made between the state of health and the state of disease, we see no rea-son for any confusion and do not need to provide an alternative mechanism for our findings. We are sure that Dr Somasundaram would be happy to agree.
