Helping patients to help themselves: the future for management of ulcerative colitis?

P Moayyedi

Guided self management of ulcerative colitis with follow up on request, compared with traditional management, accelerates treatment provision, reduces visits to specialists and general practitioners, and does not increase morbidity.

van Illich believes that “the medical establishment has become a major threat to health”. He reasons that the rise of modern medicine has encouraged a culture of dependency on the medical establishment rather than promoting self caring approaches to illness. This extreme viewpoint has a surprising number of supporters; perhaps because it contains a grain of truth. Clinicians can be paternalistic and often set up services with little regard to patient preferences or whether this is the most cost effective method of delivering health care. It is therefore refreshing to read the paper by Robinson et al comparing guided self management with usual care for ulcerative colitis (UC) patients in a randomised controlled trial. Patients were more satisfied with guided self management, and patients with relapses took steroids earlier. There was also a statistically non-significant trend for relapses to be of shorter duration. The results seem compelling, so should there be widespread implementation of this management strategy for UC?

This was a well designed and clearly reported study but inevitably some questions remain. More than 80% of participants had distal UC and only 5% were receiving azathioprine, hence the results pertain mainly to patients with left sided disease not taking long term immunosuppression. There also needs to be longer follow up as the initial enthusiasm for guided self care may diminish with time. There is therefore the danger that patients will be left without specialist input in the long term. Robinson et al will continue to monitor the new system and these results will be important.

The authors highlight the trend towards a reduction in the length of relapses in those allocated to guided self management but are rightly cautious in interpreting this finding. There was also a trend towards a greater proportion of self managed patients to relapse (61% in the guided self management arm compared with 49% in the usual care group). This was not statistically significant and may reflect the fact that relapses were self reported. However, if there were a 12% difference in relapse rates this would be clinically important.

What is clear from the data is that UC patients are dissatisfied with the current system, with a staggering 94% (80/85) of those randomised to usual management preferring another approach. It is interesting that although a large number of patients in the self management group preferred traditional management; 82% preferred self management. Health related quality of life scores were similar in the two groups and did not change during the trial.

Conclusion: Guided self management of ulcerative colitis accelerates treatment provision, reduces visits to specialists and general practitioners, and does not increase morbidity.
adopt guided self management for pa-
tients with left sided colitis in remission
and without the need for immunosup-
pression. Others may be more cautious
and want further trials from other
centres, and comparisons with other
strategies such as nurse led clinics and
telephone consultations.7

Clinical Evidence—Call for contributors

Clinical Evidence is a regularly updated evidence based journal available world wide
both as a paper version and on the internet. Clinical Evidence urgently needs to recruit a
number of new contributors. Contributors are health care professionals or epidemiologists
with experience in evidence based medicine and the ability to write in a concise and
structured way.

We are presently interested in finding contributors with an interest in the follow-
ing clinical areas:

<table>
<thead>
<tr>
<th>Angina pectoris</th>
<th>Hepatitis C</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attention deficit hyperactivity disorder</td>
<td>HIV</td>
</tr>
<tr>
<td>Genital warts</td>
<td>Influenza</td>
</tr>
<tr>
<td>Hepatitis B</td>
<td>Varicose veins</td>
</tr>
</tbody>
</table>

Being a contributor involves:

• Appraising the results of literature searches (performed by our Information Specialists) to
identify high quality evidence for inclusion in the journal.
• Writing to a highly structured template (about 1500–3000 words), using evidence from
selected studies, within 6–8 weeks of receiving the literature search results.
• Working with Clinical Evidence Editors to ensure that the text meets rigorous epidemiological
and style standards.
• Updating the text every eight months to incorporate new evidence.
• Expanding the topic to include new questions once every eight months to incorporate new
evidence.
• Expanding the topic to include new questions once every 12–18 months.

If you would like to become a contributor for Clinical Evidence or require more
information about what this involves, please send your contact details and a copy of your
CV, clearly stating the clinical area you are interested in, to Polly Brown
(pbrown@bmjgroup.com).
