If you have a burning desire to respond to a paper published in Gut, why not make use of our “rapid response” option? Log onto our website (www.gutjnl.com), find the paper that interests you, and send your response via email by clicking on the “electron” option in the box at the top right hand corner. Providing it isn’t libellous or obscene, it will be posted within seven days. You can retrieve it by clicking on “read electron” on our homepage. The editors will decide as before whether to also publish it in a future paper issue.

Living related liver transplantation: a Japanese experience and development of a checklist for donors’ informed consent

In the February 2002 issue of Gut, Broelsch et al argued for a controversial therapy of living related liver transplantation (Gut 2002; 50:134). The Japanese experience is somewhat different from those of other countries, as indicated in the article. Japan has long been the subject of sociocultural studies because of its delay in using the organs of brain dead persons for transplantation purposes. Since the Organ Transplant Law was enacted in 1997, only 16 liver transplant operations using brain dead donors have been performed at Kyoto University Hospital, and more than 1000 such transplants have taken place in Japan.

The development of this medical procedure at our institute has entailed a strict self regulatory process.

(1) Each case is reviewed by an institutional professional committee that examines the medical indication. The transplant team prioritises the safety of donors, and no donor deaths have been reported so far.

(2) Informed consent obtained by transplant teams is reassessed by the institutional ethics committee to check for the absence of coercion and guarantee the right to refuse surgery until the last moment. The ethics committee has developed a checklist (table 1) and basically all donors are interviewed by a member of the ethics committee before surgery. Donor candidates are restricted to a spouse or relatives within the third degree of blood relationship.

Table 1 Checklist for interviews with donors for living related liver transplantation

| 1. General profile of the recipient and the donor |
| (a) A brief medical history of the recipient |
| (b) Family tree |
| (2) Informed consent |
| (a) When and how did you come to know about living related donor liver transplant? |
| (b) Who explained the details of the transplant surgery, and how many times? |
| (c) Under what circumstances (one to one, or with others present)? |
| (d) Do you clearly understand the procedure of the surgery? |
| (e) Do you fully understand the risks and benefits of the treatment (including short term and long term risks for the donor, and the success rate of graft attachment for the recipient)? |
| (f) Have you been given information and explanations about alternative therapies? |
| (g) Have you been given enough time to ask questions? Have you been invited to ask questions? |
| (3) Decision making process |
| (a) Have you consulted with anyone? |
| (b) Was there any coercion by other family members or relatives? (For example, if you do not agree to be a donor, the patient will surely die.) |
| (c) Is your decision completely voluntary? |
| (4) Psychosocial aspects |
| (a) Do you have any anxiety about your surgery? |
| (b) Do you have any problems in your life [for example, business or social relationships]? |
| (c) Do you have any financial problems? |
| (5) Protection of the donor’s right |
| (a) You have the right to refuse or withdraw your consent until the last moment. |
| (b) You will not suffer any disadvantage if you decide to refuse or withdrawal. |

Interviewer’s assessment

(1) The donor is well informed. ☐Yes ☐No
(2) The donor has a good understandings of the entire process. ☐Yes ☐No
(3) The donor is fully capable of making a decision. ☐Yes ☐No
(4) The donor’s decision is completely voluntary and firm. ☐Yes ☐No
(5) The decision has been reached without any evidence of coercion. ☐Yes ☐No
(6) The donor’s right has been fully protected. ☐Yes ☐No
(7) The donor is without significant psychosocial problems. ☐Yes ☐No

Time of interview: ☐≥30 min
Interviewer’s signature (a member of ethics committee)

Endoscopic surveillance of premalignant gastric lesions

We read with interest the study by Whiting and colleagues (Gut 2002; 50:378-81). The study has further highlighted the importance of early detection of gastric cancer and also given further emphasis on ways to prevent the multistep progression in gastric carcinogenesis. However, we would like to make the following comments.

Firstly, one in five patients in this group had lesions which, according to Whiting et al, should be followed up by yearly endoscopies. Despite the low acceptance rate in screening
Smoking and ulcer healing

We read with interest the paper by Wong et al (Gut 2002;50:322–5) on prediction of therapeu-
tic failure in patients with bleeding peptic ulcer but are surprised they did not include
smoking in their logistic regression analysis. The background prevalence of smoking is suf-
iciently high in western communities to be a useful marker if found significant. The associ-
atation between smoking and ulcer healing and smoking and cardiovascular and respiratory
disease raises the issue of whether smoking may be a risk factor both for ulcer rebleeding
and mortality. It is recognised that cardiovas-
cular and respiratory mortality is a sub-
stantial contributor to peptic ulcer disease
related mortality. Addition of smoking may
improve the predictive performance of their
receiver operating curve and the value of their
“model” in clinical practice.

Oesophageal pH monitoring in Barrett’s oesophagus

We wish to comment on an interesting paper
published previously in Gut which we inadvert-
ently overlooked at the time. Fass et al (Gut 2001;48:310–13) reported that there was a
positive correlation between percentage time
that oesophageal pH was less than 4 in 24
hours with the length of the Barrett’s segment
but have now correlated oesophageal acid expo-
sion and our study of patients treated with omeprazole for up to six
years showed that none developed dysplasia1 whereas of Sontag and colleagues
in showing a correla-
tion between oesophageal acid exposure and length of Barrett’s oesophagus showed a less
quantifiable relationship.

Many studies, including our own,2 have
shown good symptomatic response to proton
pump inhibitor (PPI) therapy in patients with
Barrett’s oesophagus but without significant
regression of Barrett’s epithelium, although
approximately 30% of patients develop
squamous islands within the Barrett’s seg-
ment. Within each study to date, the same
dose of PPI has been given to each patient.
However, as oesophageal pH monitoring stud-
ies show, there is wide variation in acid reflux
between patients. Effective control of acid reflux into the oesophagus is important
in preventing dysplasia3 and our study of
patients treated with omeprazole for up to six
years showed that none developed dysplasia4
whereas of Sontag and colleagues
in showing a correla-
tion between Barrett’s length and supine
reflux.

Author’s reply

I would like to thank Drs Neumann and
Cooper for their comments on our article on
the correlation of oesophageal acid exposure
with Barrett’s oesophagus length (Gut 2000;49:310–13). In recent years, gastro-
enterology has focused on factors that promote
the development of Barrett’s oesophagus. Surpris-
ingly, our understanding of the mechanisms
that are responsible for the emergence of Bar-
ett’s epithelium remains extremely poor.

www.gutjnls.com
Barrett’s patients as those with long and short segment Barrett’s oesophagus, we believe that the specific length of Barrett’s epithelium might be the key for unlocking the mystery of Barrett’s evolution. Consequently, we have initiated several research projects that were designed to elucidate the role of acid reflux in determining the specific length of Barrett’s oesophagus.

The results of the above mentioned study have been confirmed by other investigators.2, 3 Oberg et al have also demonstrated that the extent of Barrett’s mucosa is inversely correlated with lower oesophageal sphincter pressure and length.3 Furthermore, we recently reported that the size of hiatal hernia correlated with the length of Barrett’s oesophagus (r=0.62, p=0.0012).2 The last two studies suggest that the longer the Barrett’s oesophagus the higher the likelihood of finding more severe oesophageal anatomical abnormalities that are strongly associated with increased oesophageal acid exposure.

In another study from our laboratory, Tharalson et al have demonstrated a significant correlation between the rate of change in acid exposure along the oesophagus and the length of Barrett’s oesophagus, using a pH probe with four sensors located 5 cm apart.7 The study investigated the rate at which reduced glutathione concentrations increase from the proximal to the distal oesophagus. This increase in acid exposure along the oesophagus and the length of Barrett’s oesophagus increases as the rate of acid exposure increases.

Presently we are not clear if acid reflux is the sole determining factor for Barrett’s appearance. It is likely that other factors, such as bile reflux, might have a synergistic effect. However, the role of bile reflux in determining the length of Barrett’s oesophagus remains to be elucidated.

We agree with Drs Neumann and Cooper that due to the close relationship between length of Barrett’s mucosa and oesophageal acid exposure, patients with longer Barrett’s epithelium might fail to acquire higher doses of proton pump inhibitors to normalise their oesophageal acid exposure. One should be prepared to increase the dose of proton pump inhibitors in patients with longer segments of Barrett’s oesophagus if normalisation of oesophageal acid exposure is desired (not only symptom control).

Influence of clinical factors, drug use, and food intake on the glutathione system

In a previous issue of Gut, Hoensch and colleagues (Gut 2002;50:235–40) using antral and duodenal biopsies, reported on a variety of factors such as sex, age, drug use, and food intake that influence the concentration of glutathione and the activity of glutathione S-transferase. All of these factors either singly or in combination significantly affect glutathione metabolism within the gastric mucosa.

Curiously, one critical factor that may have influenced their measurements, namely Helicobacter pylori infection, was not mentioned in their paper. This omission is particularly important as the majority of patients that these investigators examined had endoscopic findings strongly suggestive of infection with H pylori (gastriic erythema, erosions, or ulcers). Previous studies by some of the coauthors in the Hoensch paper1 as well as by others have clearly demonstrated that H pylori infection is associated with marked depletion by approximately 50% of reduced glutathione within the gastric epithelium, and that concentrations of reduced glutathione in the antral and corpus glandular epithelium are restored to normal by eradication of H pylori. Failure to stratify patients for H pylori infection makes other conclusions in the study less compelling.

Intra- and extracellular oxidative stresses induced by H pylori in association with depletions of glutathione and/or genetic polymorphisms of enzymes that control its metabolism may compromise normal epithelial cell function and enhance susceptibility to gastric cancers. In considering the gastric glutathione system, the effect of H pylori should not be ignored.

We appreciate very much the comments made by Shirin et al concerning our publication (Gut 2002;50:235–40).

In our study (Gut 2002;50:235–40), we investigated a wide variety of factors which had not been evaluated entirely at the time this paper was written. In the meantime, the reported new findings of our group on H pylori were discovered in another patient population from the Netherlands.3, 7

After we received the comments of Shirin et al, we looked again at the data of our patients from Germany to test for H pylori. We found that H pylori had a significant effect on one of the parameters of the gastrointestinal glutathione (GSH) system. The level of glutathione S-transferase (GST A) (alpha) in the antral mucosa was significantly depressed (p<0.05) in H pylori infected patients (4.8 (7.3) µg/mg cytosomal protein (n=63) vs 5.6 (6.9) (n=60). The values given are means (SD) using the Wilcoxon test for comparison of means.

The status of H pylori infectivity was determined in the gastric mucosal biopsy specimens using the urease test which was read as either positive (H pylori present) or negative (H pylori absent) from the colour reaction (CLO test).

The other parameters (GSH concentration, GST enzyme activity, levels of GST P (pi) and GST T (theta)) were not affected in the antral mucosa. Eradication of H pylori negative (H pylori) antral specimens using the urease test which was performed in patients with ulcers and erosions but these patients were not followed up by endoscopy routinely.

H pylori was the only factor that had a significant depressive effect on antral GST A level. H pylori had no influence on duodenal GST A, GST P, or antral GST T1, which confirms that vegetable and fruit stimulation of these enzymes was not confounded by H pylori.
However, it has to be considered that H pylori evaluation and eradication in patients from the Netherlands were done only in non-ulcer dyspepsia while patients from Germany comprised various pathological endoscopic diagnoses apart from non-ulcer dyspepsia.

Our cross sectional study confirms that H pylori seems to depress the GST A component of the enzymatic GSH system in the antral mucosa of the stomach. Depression of GST A levels could mean increased susceptibility of the stomach mucosa towards carcinogenic insults.

Mycobacterium avium subspecies paratuberculosis as a cause of Crohn’s disease

The debate by Professor Quirke (Gut 2001;49:757–60) was an interesting review of the hypothesis of a microbiological aetiology of Crohn’s disease. He indicates that “the hypothesis remains controversial and unproven.”

The point is that proof is never absolute, and indeed the objective of research is to disprove the hypothesis rather than to prove it, the latter being an impossible objective, and scientifically flawed. He goes on to mention that “for the infectious disease hypothesis to be proved for any organism, Koch’s postulates need to be fulfilled.” This is not correct. Proof is pragmatic not absolute, and in practice it is the fulfilment of a set of predetermined objectives. Koch’s postulates are but an example of this, the Euclidian principle of quod erat demonstrandum, and an extremely important development of scientific philosophy of the 19th century. Koch himself however recognised the weakness of his postulates in that although he felt that cholera was microbiological in causation, he was unable to apply his postulates to it.

It is important to review Koch’s postulates and they are as follows:

(1) “The specific organism should be shown to be present in all cases of animals suffering from a specific disease but should not be found in healthy animals”

This postulate demands a high level of sensitivity of laboratory methods and the clinicopathological identification of a specific disease—can Crohn’s disease be classified as such? At the time of Koch the important concept of a commensal microbe was not developed.

(2) “The specific microorganism should be isolated from the diseased animal and grown in pure culture on artificial laboratory media”

This demands laboratory methods which have not always been achieved at the present time.

(3) “This freshly isolated microorganism, when inoculated into a healthy laboratory animal, should cause the same disease seen in the original animal”

Animal models are not always available for postulated microbial disease and it is recognised that transgenic transmission might cause a different disease.

(4) “The microorganism should be re-isolated in pure culture from the experimental infection”

Once again, laboratory cultures are not always possible at present.

Koch was a great scientist and he recognised so well that there was more to microbiological explanation for disease than his postulates, which have a very high level of specificity but a very low level of sensitivity. I am afraid that microbiological science must look beyond Koch’s postulates for its “proofs” and we must rethink the concepts of proof for the newly recognised microbiological diseases in the present century.

In that there is no such thing as absolute proof, science works in paradigms. These are models which come to be accepted as the best explanation of the phenomena that we see around us. However, there is no real paradigm for Crohn’s disease. I remember farfetched “psychosomatic” concepts in the 1960s, to be replaced by food allergy during the latter part of the 20th century. But these paradigms have fallen into disfavour, being replaced by a lack of any clear idea of the type of disease that we are dealing with in respect of Crohn’s disease. Genetic factors are probably an influence only on susceptibility but not causation.

But in the treatment of patients clinical doctors require a paradigm on which to base explanations and understanding, treatment, and research. The nearest we have to a paradigm of causation of Crohn’s disease is that it is “inflammatory”, and so conforming to the allopathic principle of curantur quod est curandum, and an extremely important development of scientific philosophy of the 19th century. Koch himself however recognised the weakness of his postulates in that although he felt that cholera was microbiological in causation, he was unable to apply his postulates to it.

What therefore do we think of the pathology of Crohn’s disease? Indeed we often are, to be totally sceptical regarding a concept of proof of microbiological causation and then continue to think as to whether it is plausible that the disease might be microbiological, even in the absence of a definite microbe. The development of the paradigm and identification of a specific microbe are different scientific processes.

Plausibility is founded on existing knowledge and models, based on epidemiology and pathology, the main foundations of Western clinical medicine. What therefore do we think of the pathology of Crohn’s disease? Firstly, it is clear that Crohn’s disease is not a homogeneous disease but a variety of different patterns of inflammatory disease of the intestinal tract. The hallmark of Crohn’s disease is firstly a patchy inflammation of the gastrointestinal tract, including perianal perianal areas of skin. Granulomas are another hallmark and fissuring a third. We can go on in this way but the more criteria that we add, the more it would appear that the disease is a heterogeneous group. We cannot define Crohn’s disease, we do not really know what it is, and so a concept of causation is going to be based on a very fragile foundation.

However, we can make progress, especially if we look at the classical type of Crohn’s disease involving the right side of the colon, the caecum, and the terminal ileum, with fissuring and granulomatous disease. This type of disease looks very much like tuberculosis, so much so that if it presents in an Asian patient the disease is usually called tuberculosis whereas if it presents in a non-Asian patient it is usually called Crohn’s disease. It seems that the similarities to tuberculosis are so powerful, then clearly causation is likely to be very similar. A further important feature is the epidemiological observation of family clustering around us. However, there is no real paradigm of a microbiological causation whereas others see no practical advantage of this and are happy to remain without a paradigm other than “inflammatory bowel disease”. Response to one or more given antibiotics cannot be laid down as a criterion of proof of microbiological causation but would help strengthen the paradigm. What we need to do in respect of Crohn’s disease is consider which is the most plausible hypothesis and then continue to test it in this case with microbiological scientific efforts, the importance of which Professor Quirke emphasises. As with every other paradigm in science, it must be under continual review and we must always be prepared to reconsider our paradigm of causation. Although we can always be wrong, and indeed we are often, to be totally sceptical denies the opportunities for scientific progress. Research must be based on hypothesis and paradigm.

Modern Management of Cancer of the Rectum

This is a remarkable little book. A brief review of contributors will whet the appetite: a quick read of the first chapter by Drs Shelton and Goldberg will soon confirm your decision to buy. This initial chapter is an engaging review of the key writings of the leaders of surgical thought over the centuries and provides a rare insight into how we have arrived where we are today. The book continues with the rich but often too brief reviews of the many components of the colorectal cancer scene. This is the most important of all of the human cancers as we already know enough to cure more people of bowel cancer than all of the other internal cancers put together. Nevertheless, even though we know the disease, these chapters are well written. Nevertheless, even in those difficult areas, the writers have a constant sense of direction which I consider spurious the argument which I would personally prefer to read about the strength of the argument for chemotherapy given postoperatively. Many oncologists, well aware of the enormous amounts of operative chemo radio therapeutic onslaught norm and the probable future for rectal cancer, would personally prefer to read about honest controversy and to see current American dogma questioned rather than reinforced.

These few criticisms are offered as a surgeon's affectionate commentary on an essentially splendid little book with something worthwhile for all serious doctors in the field of rectal cancer.

R J Heald

Management of Chronic Viral Hepatitis

Management of Chronic Viral Hepatitis is an A5 sized multi-author textbook of over 300 pages which forms one of eight books in a gastrointestinal and hepatology series. Curiously, the only other hepatological title in this series is a book entitled Viral Hepatitis: Diagnosis, Treatment, Prevention by a different author. The stated intention of the book is to bring the recent advances in clinical and basic research into the doctor's office. Through the use of clinical vignettes, it seeks to highlight some of the recent advances in the treatment of viral hepatitis and to demonstrate how these treatments are incorporated into everyday practice. This is a good idea, which works well, particularly in those chapters concerning treatment. In addition to looking at the general treatment of viral hepatitis, the book also has informative chapters on specific disease subsets such as those with chronic hepatitis C and normal alanine aminotransferase levels or those with human immunodeficiency virus (HIV) and hepatitis C virus (HCV) coinfection. The authors include an interesting sounding chapter on alternative therapies for hepatitis C but this focuses primarily on conventional antiviral treatments that have been shown to be of little or no benefit for hepatitis C and disappointingly only touches on the frequently used alternatives such as herbal products and glycyrrhizin.

There are several chapters on hepatitis B virus (HBV) covering treatment, future treatments, managements, while quite short and inconsequential. This manages to be both practical and informative. The opening chapter covers the basics including choice of probe, use of coupling gel, patient preparation, and scanning positions. However, the opening chapters there is surprisingly little reference to the management of the widespread pre-core mutant strain.

Additional chapters cover diagnostic techniques and some molecular virology. The chapter on HBV virology and the review of various molecular mechanisms that can be used as targets for antiviral treatment included in the chapter on future HCV therapy were particularly well written. The pace of change in viral hepatitis is fast, and as ever with multiauthor texts, delays are inevitable between writing and publishing. There are several indicators that the publishers have tried to keep this delay to a minimum, such as the figures that have clearly been lifted straight out of someone's powerpoint slide presentation, the references that are left in a reference manager format, and a few minor inaccuracies in the text. Despite these measures to speed publication, there have been predictable advances in treatment that are not well covered, such as the rapidly accumulating data on the efficacy of pegylated interferon alpha in combination with ribavirin in the treatment of hepatitis C.

Despite these criticisms, there are a number of very good chapters and the book provides a good overview and a fairly up to date understanding of hepatitis and its management. The target audience is hard to define but anyone involved in looking after patients with viral hepatitis will find something of use. For those new to viral hepatitis this is a helpful textbook that shows how an understanding of both the natural history and treatment options should be used to guide management decisions.

M Cramp

Abdominal Ultrasound

Mike Stocksley moved from a career in clinical ultrasound to teaching and is now senior lecturer in the Faculty of Health at South Bank University. His background as an educator is readily apparent in this excellent book which for him was clearly a labour of love.

Despite the increasing complexity of investigations available, ultrasound remains an important tool in the investigation of abdominal pathology. Its ready availability and resulting popularity do not however imply that it is a straightforward or simple skill. It is probably the most operator dependent imaging modality, and mastery of the underlying concepts, proper performance of a scan, awareness of normal appearances, detection of relevant findings, and their correlation into a unifying diagnosis requires not only appropriate training but also extensive hands-on experience. These factors are often under appreciated by physicians, and if there is one thing guaranteed to aggravate the busy radiologist, it is a request for a “quick ultrasound” or for one to “just have a look”.

Mr Stocksley clearly appreciates the complexities of the topic and has produced a book which is, in quite short and concise, manages to be both practical and informative. The opening chapter covers the basics including choice of probe, use of coupling gel, patient preparation, and scanning positions. The chapter on Doppler ultrasound; reading this chapter caused the reviewer to hopefully wish that Mr Stocksley had a presence in close proximity while he was studying for his part 1 FRCR physics! Having dealt with the basics, the book proceeds with the nitty gritty of practical abdominal ultrasound and there are excellent chapters on the “usual suspects”: the liver, biliary tree, pancreas, spleen, and urinary tract, as well as money expended on chemotherapy and radiotherapy given postoperatively. Many serious oncologists, well aware of the strength of the argument for chemotherapy after colon cancer resections, nevertheless seriously doubt its value for rectal cancer. Minsky et al in an otherwise superb review of chemotherapy dismiss on grounds which I consider spurious the argument that better surgery may make some patients better managed without chemotheraphy.

www.gutjnl.com
more esoteric subjects such as the adrenal glands, muscle, and bowel. Each chapter is laid out similarly, with an initial description of functions and anatomy of the organ followed by the optimal scanning technique and normal ultrasound appearances before a discussion of pathology. The book is lavishly illustrated with over 250 illustrations, including line drawings, photographs to demonstrate scanning positions, and ultrasound images, with a nice balance between normal and pathological appearances. Advice boxes scattered throughout the text give useful tips on pitfalls to avoid, measures to improve scanning technique, and the relevance of findings.

Quibbles with this book are relatively minor. I would have welcomed a chapter on endoscopic ultrasound including endoanal; this area is underrepresented in the text. Also, one feels the clinical advice is in places oversimplistic: for example, in a table on abdominal pain, stating that “pain in both left sides and right=cancer” is of limited value. The impression that this book is predominantly aimed at ultrasonographers in training is reinforced by emphasis on such topics as planning an ultrasound room and report wording. However, these caveats aside, this is an excellent book in training is reinforced by emphasis on such topics as planning an ultrasound room and report wording. However, these caveats aside, this is an excellent book.

**CORRECTION**

Due to an error in the production process, parts B and C of figure 2 in the paper by Ruemmele et al in the December issue of the journal (Gut 2002; 51:842–8) were printed incorrectly. The figure is reprinted here.

**NOTICES**

**Sir Francis Avery Jones BSG Research Award 2003**

Applications are invited by the Education Committee of the British Society of Gastroenterology who will recommend to Council the recipient of the 2003 Award. Applications (TWENTY COPIES) should include:

- A manuscript (2 A4 pages only) describing the work conducted
- A bibliography of relevant personal publications
- An outline of the proposed content of the lecture, including title
- A written statement confirming that all or a substantial part of the work has been personally conducted in the UK or Eire.

Entrants must be 40 years or less on 31 December 2002 but need not be a member of the Society. The recipient will be required to deliver a 30 minute lecture at the Annual meeting of the Society in Birmingham in March 2003. Applications (TWENTY COPIES) should be made to the Honorary Secretary, British Society of Gastroenterology, 3 St Andrews Place, London NW1 4LB by 1 December 2002.

**Broad Medical Research Program—Inflammatory Bowel Disease Grants**

Funds for inflammatory bowel disease (IBD) research are available immediately from the Broad Medical Research Program of The Eli and Edythe L. Broad Foundation for innovative projects regarding etiology, therapy, or prevention. Grants totaling approximately US$100,000 per year are available for basic or clinical projects. Larger requests may be considered. Initial letter of interest (no submission deadline), simple application, rapid (60 day) peer review, and funding. Criteria for funding includes new ideas or directions, scientific excellence, and originality. Early exploratory projects, scientists not currently working in IBD, and/or interdisciplinary efforts are encouraged. Further information: Marciana Poland, Research Administrator, Broad Medical Research Program, 10900 Wilshire Blvd., 12th Floor, Los Angeles, CA 90024-6352, USA. Tel: +1 310 954 5091; email: info@broadmedical.org; website: www.broadmedical.org

**The national register of hepatitis C infections with a known date of acquisition.**

The register steering group invite clinical and epidemiological researchers to submit proposals to access data held in the register. It is envisaged that a variety of studies might benefit from linkage with or access to the register, and proposals from all specialties and institutions are welcomed. Any researchers interested in applying for access to information held within the national register should contact the register co-ordinator (see below) for a list of available data and an application form. Study proposals should then be submitted to the register co-ordinator by 16 December 2002.

Further information: Dr Helen Harris (Register Co-ordinator) or Ms Lisa Beck (Research Assistant), Immunisation Division, Communicable Diseases Surveillance Centre, Public Health Laboratory Service, 61 Colindale Avenue, London NW9 6EQ. Tel: +44 (0)20 8200 6686 ext 4496; fax: +44 (0)20 8200 7866; email: hharris@phls.nhs.uk or lbeck@phls.nhs.uk

**17th International Workshop on Therapeutic Endoscopy**

This will be held on 3–5 December 2002 in Hong Kong. Further information: Professor SC Sydney Chung, Endoscopy Centre, Prince of Wales Hospital, Shatin, NT, Hong Kong. Tel: +852 2632 2233; fax: +852 2635 0075; email: info@hksde.org

**Advances in the Inflammatory Bowel Diseases**

This conference will take place on 6–7 December 2002 in New York, USA. Further information: Heather Drew, Imedex, 70 Technology Drive, Alpharetta, GA 30005-3969, USA. Tel: +1 770 751 7332; fax: +1 770 751 7334; email: h.drew@imedex.com; website: www.imedex.com

**15th European Intensive Course (SMIER) Digestive Endoscopy**

This course will take place on 16–17 December 2002 in Strasbourg, France. Further information: Michele Centonze Conseil, 6 bis Rue des Cendriers, 75020 Paris, France. Tel: +33 1 44 62 68 80; fax: +33 1 43 49 68 58.
The Future of Gastro-entero-hepato-pancreatology is bright
This Academic Farewell Symposium of Guido NJ Tyticat will be held on 12 December 2002 in Amsterdam, the Netherlands. Deadline for registration is 1 November 2002 (no registration fee) and registration should be done via email to: j.goedkop@amc.uva.nl.

Cancer of Oesophagus and Gastric Cardia: from Gene to Cure
This conference will be held on 13–15 December 2002 in Amsterdam, The Netherlands. Further information: European Cancer Centre, PO Box 9236, NL 1006 AE Amsterdam, The Netherlands. Tel: +31 (0)20 346 2547; fax: +31 (0)20 346 2525; email: ecc@ikca.nl

Imaging of the Abdomen: an Update
This will be held on 23–24 January 2003 in Amsterdam, the Netherlands. Further information: visit the website www.epgs.nl or email epgs@amc.uva.nl. Tel: +31 20566 3926/4386.

The Sheila Sherlock Memorial Symposium
Dame Sheila Sherlock, who died earlier this year, was responsible for creating hepatology at the Royal Free Hospital, London. This memorial symposium will take place on 26–28 January 2003 at the Royal Free Hospital, London, UK.
