An immunodominant DQ8 restricted gliadin peptide activates small intestinal immune response in vitro cultured mucosa from HLA-DQ8 positive but not HLA-DQ8 negative coeliac patients

G Mazzarella, M Maglio, F Paparo, G Nardone, R Stefanile, L Greco, Y van de Wal, Y Kooy, F Koning, S Auricchio, R Troncone

**Background:** Studies on intestinal T cell clones from the mucosa of patients with coeliac disease have led to the identification of immunogenic gliadin epitopes. One is HLA-DQ8 restricted, its recognition by T cells being increased by introduction of negatively charged residues operated by tissue transglutaminase.

**Aim:** To test HLA-DQ8 restricted epitope in both native (QYPSGQGSFQPSQQNPQA) and deamidated (QYPSGEGSFQPSQGENPQA) forms in an organ culture system of treated coeliac mucosa from HLA-DQ8 positive and HLA-DQ8 negative patients.

**Patients and methods:** Jejunal biopsies obtained from 10 patients with coeliac disease (six HLA-DQ8 positive and four HLA-DQ8 negative) were cultured in vitro with a peptic-tryptic digest (PT) of gliadin, or with the native (peptide A) or deamidated (peptide B) peptide. Intraepithelial CD3+ and lamina propria total CD25+ CD4+ and CD25+ CD8+ cells were counted, lamina propria intercellular adhesion molecule 1 (ICAM-1) expression was evaluated, as well as that of Fas molecules on epithelial cells.

**Results:** In HLA-DQ8 positive, but not in HLA-DQ8 negative, coeliacs the density of intraepithelial CD3+ cells, lamina propria total CD25+ and CD25+ CD4+ cells were counted, lamina propria intercellular adhesion molecule 1 (ICAM-1) expression was evaluated, as well as that of Fas molecules on epithelial cells.

**Conclusion:** These data show that the DQ8 restricted gliadin peptide is immunogenic only in the intestinal mucosa of HLA-DQ8 positive coeliac patients in both native and deamidated forms.

**References**

1. Celiac disease (CD) is one of the most thoroughly investigated and characterised of the many forms of food intolerance. It is defined as a permanent intolerance to wheat gliadins and related prolamine responsible for enteropathy in genetically susceptible individuals. Architectural changes, phenotype of lamina propria mononuclear cells, and pattern of cytokines indicate a predominance of the Th1 response. Susceptibility to CD is determined to a significant extent by genetic factors: a great part of the genetic susceptibility maps to the HLA region on chromosome 6 as approximately 95% of CD patients carry an almost identical HLA-DQ2 heterodimer (DQA1*0501 DQB1*0201). In most of those individuals negative for this haplotype the disease is associated with the class II alleles DQA1*0301 and DQB1*0302 that encode a DQ8 molecule which is linked to DR4 haplotypes.

Recent studies on intestinal T cell clones from the CD mucosa have led to the identification of a few immunogenic gliadin epitopes. Three are clearly HLA-DQ2 restricted; one is HLA-DQ8 restricted and its recognition by T cells is increased by introduction of negatively charged residues operated by tissue transglutaminase.

**Organ culture of the small intestine** is a valuable model to study the immunological events occurring in the coeliac mucosa following contact with gliadin peptides; in fact, it has been shown that the in vitro gliadin challenge system reproduces many features of the mucosal immune response which occur in the established coeliac lesion. It has been proposed that gliadin challenge may initiate two parallel pathways, one of which leads to T cell activation and another that precedes it. Epithelial cells overexpress HLA-DR molecules within two hours, and in a second stage, T lymphocytes become fully activated; moreover, T lymphocytes migrate in the upper mucosal layers; T lymphocytes that migrate in the higher lamina propria compartments are mainly CD4+ and show markers of activation; and migrating intraepithelial lymphocytes are CD8+ and do not express these markers. The organ culture system has already been used to characterize gliadin epitopes able to activate mucosal T cells mediated immunity.

The aim of this study was to test the HLA-DQ8 restricted gliadin epitope, in both native and deamidated forms, in an organ culture system.

**MATERIALS AND METHODS**

**Patients and HLA typing**

Ten patients with CD (four male and six female; median age 24 years (range 13–45)), diagnosed on the basis of revised ESPGHAN criteria, were recruited. They were on a gluten free diet for at least two years; they showed normal small intestinal histology and negative serology (anti-gliadin and antigliadomysium).

Molecular typing was performed as previously described. Briefly, DNA extraction was carried out according to a rapid
extractive method. Amplification of the polymorphic second exon of DRB1, DQA1, and DQB1 genes, and dot blot analysis of amplified DNA with sequence specific oligonucleotides probes was carried out. HLA typing of patients is reported in Table 1. Six patients were DQ8 positive but three were also DQ2 positive. Four patients were DQ2 positive, all being DQ8 negative. Here, the first six will be referred to as DQ8 positive and the remaining four as DQ8 negative.

**Peptides**

A peptic-tryptic digest (PT) of gliadin (variety S Pastore, gift of Dr De Vincenzi, Istituto Superiore di Sanita’, Rome, Italy) was used as a positive control. Peptide A corresponds to the residues 203–220 (sequence QYPSGQGSFQPSQQNPQA of gda09, SwissProt P18573). Its deamidated form (peptide B) presents two residues of glutamine converted to glutamic acid (peptideB 1 mg / ml) peptide. The dishes were placed in a sterile anaerobic jar which was gassed with 95% oxygen/5% carbon dioxide and incubated at 37°C. After 24 hours of incubation at room temperature, sections were incubated for 30 minutes with rabbit antimouse serum (Dako, Milan, Italy) and for a further 30 minutes with APAAP complex to stain CD25 positive cells and intercellular adhesion molecule 1 (ICAM-1) positive cells, or with PAP complex (Dako) to stain CD3 and CD95 (Fas) positive cells. Slides were washed in TBS for 10 minutes following each antibody incubation and were developed by a final incubation of five minutes with 2 amino-9 ethyl-carbazole (Sigma) when the PAP complex was used; when the APAAP complex was used instead, the immune reaction product was developed by stirring continuously for three minutes with 20 mg of naphthol-AS-biphosphate in 0.5 ml N-N-dimethylformamide added to 0.2 ml of sodium nitrite (Sigma Chemical Company, St Louis, Missouri, USA), 0.08 ml of New Fucsin (Merck, West Point, Pennsylvania, USA), 40 ml of TBS, pH 8.7, and 17.5 mg of Levamisole (Sigma). Omission of the primary antibody served to control against non-specific antibody binding. The sections were finally stained with Mayer’s haematoxylin and mounted. Non-immune mouse immunoglobulins at the same isotype were used as the primary antibody for control of specificity. In experiments to detect activated T cells (CD3+CD25+), immunofluorescence with confocal microscopy was used because it allows better resolution of three colour procedures. Cryosections were fixed in acetone and incubated for one hour at room temperature with a mixture of mouse monoclonal antibodies anti-CD25 human (Dako, 1:25) and rabbit polyclonal anti-CD3 human (Dako, 1:100), followed by a mixture of horse antimouse FITC conjugated (1:200, Vector Laboratories, California, USA) and swine antirabbit TRITC conjugated (Dako, 1:300). These antibodies were applied for 45 minutes in the dark followed by incubation (30 minutes) with ToPro-3 (Molecular Probes Leiden, the Netherlands) for counterstaining the nuclei. Finally, sections were mounted in phosphate buffered saline (PBS); glycercol (1:1). The primary and secondary antibodies were diluted appropriately in PBS containing bovine serum albumin at 1%, and all incubations took place at room temperature with intervening 10 minute PBS rinses.

CD3+ and CD25+ immunofluorescence cells were imaged with a Leica SP confocal microscope (Germany) using a 40× Plan-Neofluar oil immersion objective. The illumination source was from three single lasers: 488 nm line from argon ion laser, 543 nm line from HeNe ion laser, and 633 nm line from HeNe ion laser.

**Morphometric analysis**

The density of cells expressing CD3 in the intraepithelial compartment was determined by counting the number of stained cells as a percentage of 100 enterocytes; the number of CD3

Statistical analysis
The Student’s two tailed t test was used to compare specimens exposed to gliadin or synthetic peptides with those exposed to medium alone for the same incubation time. Non-parametric tests (Wilcoxon two tailed) were also applied and the results are concordant with those obtained using parametric tests.

**RESULTS**

**Effects of in vitro HLA-DQ8 restricted peptide challenge on T cell activation**
For both HLA-DQ8+ and HLA-DQ8− coeliac patients, in jejunal biopsies cultured in the presence of a PT digest of gliadin, the number of cells/mm² expressing the interleukin 2 receptor (CD25 cells) (mean (SD) 121 (40) and 113 (15), respectively) was significantly (p<0.001) higher than in those cultured in medium alone (28 (6) and 26 (8), respectively) (fig 1). However, only in HLA-DQ8+ coeliaics was the number of CD25+ cells in specimens cultured in the presence of native peptide (139 (22)) or deamidated peptide (124 (21)) significantly higher (p<0.001) than in those cultured in medium alone. In fact, no significant differences were noted in HLA-DQ8− coeliac patients between biopsy specimens cultured with native peptide (37 (2)) or deamidated peptide (38 (10)) and those cultured in only medium (26 (8)) (fig 1). In further experiments, we examined the increase in CD3+CD25+ cells; in fact, both HLA-DQ8+ and HLA-DQ8− coeliac patients challenged in vitro with the PT digest of gliadin showed a significant increase (p<0.01) in activated T cells; nevertheless, only HLA-DQ8+ coeliac patients showed a significant increase (p<0.05) of CD3+CD25+ cells in response to native or deamidated peptide (table 3, fig 2).

Expression of ICAM-1 was also evaluated to find further evidence of activated mucosal cell mediated immunity. ICAM-1 was increased significantly in all cells and vessels of biopsy specimens from HLA-DQ8+ (p<0.001) and HLA-DQ8− (p<0.01) coeliac patients cultured for 24 hours with PT gliadin compared with those cultured with medium alone; in contrast, only in coeliac HLA-DQ8+ was ICAM-1 expression...
effects of in vitro HLA-DQ8 restricted peptide challenge on Fas epithelial expression

Epithelial expression of Fas, particularly evident in basolateral membranes of enterocytes, was increased after 24 hours of challenge with PT gliadin, both in biopsy samples obtained from HLA-DQ8 (p<0.001) and HLA-DQ8 (p<0.01) coeliac patients compared with samples cultured in the presence of medium alone (fig 5). Also, significantly enhanced expression was seen when HLA-DQ8 coeliac biopsies were cultured with samples in the presence of DQ8 restricted peptide (p<0.001) compared with those cultured in medium alone (fig 5). This phenomena was specific for HLA-DQ8 coeliac patients; in fact, no significant differences were noted when Fas expression was evaluated in biopsies of HLA-DQ8 patients cultured in the presence of the DQ8 restricted peptides (both native (26 (8) and deamidated (25 (4)) compared with those cultured in medium alone (21 (8)) (fig 6).

Effects of in vitro HLA-DQ8 restricted peptide challenge on T cell infiltration

A significant increase in CD3 intraepithelial lymphocytes was seen in HLA-DQ8 biopsies cultured in the presence of the PT digest of gliadin (54 (19)) (p<0.001), native peptide (54 (19)) (p<0.001), or deamidated peptide (44 (20)) (p<0.01) compared with those cultured in medium alone (23 (9)) (fig 4). In HLA-DQ8 coeliac patients, a significant (p<0.01) increase in CD3 intraepithelial lymphocytes was seen only in biopsy specimens cultured in the presence of gliadin (42 (12)). In fact, no significant differences were noted in the number of CD3 intraepithelial lymphocytes when biopsies of HLA-DQ8 patients were cultured in the presence of the DQ8 restricted peptides (both native (26 (8) and deamidated (25 (4)) compared with those cultured in medium alone (21 (8)) (fig 4).

**DISCUSSION**

Most evidence suggests that a decisive role in the pathogenesis of coeliac disease is played by HLA-DQ2 and/or DQ8 restricted...
Immunodominant DQ8 restricted gliadin peptide in coeliac patients

Figure 6  Fas expression in the epithelium of jejunal mucosa from a DQ8+ coeliac patient cultured in vitro with medium only (A) or with native peptide (peptide A) (B). In the latter, intense staining is detected in almost all of the epithelial cells; expression is particularly evident in basolateral membranes of enterocytes. A similar pattern was observed when the mucosa was cultured with the deamidated peptide or with the peptic-cryptic digest of gliadin. Original magnification x100.

Our data showed that the DQ8 restricted gliadin epitope, identified for its activity on T cell clones, was also active in the organ culture system of the treated coeliac mucosa. In this system, it significantly increased the density of lamina propria mononuclear cells and in particular T cells expressing the interleukin 2 receptor. The extent of the latter phenomenon, which is accompanied by a redistribution of these cells, recruited in the subepithelial compartment, is of similar amplitude to that observed in cultures performed in the presence of the whole gliadin PT digest. The most likely explanation is that the peptide used is certainly immunodominant but it is also possible that activation of T cell clones specific for that peptide is followed by a bystander activation of other mononuclear cells; in fact, in our culture system, following gliadin stimulation, the dominating CD25+ subset was represented by CD3-CD25+ cells, the latter being presumably activated macrophages.

We have also observed significant enhancement of expression of ICAM-1 in those fragments cultured in the presence of the peptide. The latter phenomenon has already been described in treated coeliac biopsies cultured with a gliadin digest and is attributed to the strong γ-interferon induction which is one of the main features of this in vitro response. Moreover, two other phenomena have been observed in our biopsies cultured with the peptide: increased intraepithelial density of CD3+ cells and enhanced expression of Fas molecules on epithelial cells. The first of such observations is a phenomenon already shown to occur in vitro in response to gliadin; as it was not affected by the presence of CTLA4-Ig, a molecule interfering with costimulation of T cells, its T cell dependence has been questioned, and a pathway parallel to that involving mucosal T cells has been hypothesised. Similar observations have been made for induction of Fas for which a direct effect on epithelial cells (non-T cell mediated) has been suggested. Yet, it is still possible that CD3 epithelial infiltration is a consequence of lamina propria T cell activation. In fact, in explants of human fetal gut, small intestine T cell activation by anti-CD3 antibodies induced a significant increase in intraepithelial lymphocytes, suggesting that it might be a consequence of lamina propria T cell activation. More difficult to explain is Fas expression on epithelial cells as there is no previous evidence suggesting the influence of T cell activation on such phenomenon, which in our experience seems to be DQ restricted. The relatively large amount of peptide used in the system must also be considered in interpreting the results.

No differences were noted between the native or deamidated form of the peptide when all in vitro responses were analysed. Both peptides may be active, even if to different extents, as suggested by T cell clones studies. The relatively large amount used in the organ culture system could allow even the non-deamidated peptide to activate T cells; in this case, deamidation would not be crucial. In the alternative hypothesis, only the deamidated peptide is active; as deamidation is likely to take place during organ culture, fragments cultured with the non-deamidated peptide would eventually become activated. Experiments aimed at blocking in situ tissue transglutaminase activity could help to establish the possible role of mucosal deamidation of the native peptide.

In conclusion, we have evidence that a peptide identified and characterised for its activity on T cell clones isolated from....
coeliac mucosae is also active, in a HLA-DQ restricted manner, in an in vitro organ culture system, causing T cell activation, intraepithelial migration of T cells, and preapoptotic phenomena. The organ culture system is confirmed as very useful in determining the biological activity of gliadin peptides, before the ultimate proof of their toxicity is provided by challenge studies.

ACKNOWLEDGEMENTS

This study was carried out with financial support from the Commission of the European Communities, specific RTD programme “Quality of Life and Management of Living Resources”,QLK1-CT-1999-00037. Evaluation of the prevalence of coeliac disease and its genetic components in the European population. This work was partly supported by the “Istituto Superiore di Sanità’: Sorveglianza degli effetti nocivi da alimenti: intolleranza ai cereali (Convenzione 98/JK/T3)”. The technical help of Mr C. Meccariello and Dr L. Cipriano (Institute of Food Science and Technology, CNR Avellino, Italy) is gratefully acknowledged.
