High magnification chromoscopic colonoscopy as a screening tool in acromegaly

We read with great interest the paper by Jenkins et al (Gut 2002;51:V13–14) regarding screening guidelines for colorectal cancer (CRC) and polyps in patients with acromegaly and the subsequent discussion by Rennie addressing screening inconsistencies compared with other high risk groups.  The optimal colorectal screening modality and frequency in this group however requires clarification. Colonoscopy in this patient group is technically demanding and often complicated by inadequate bowel preparation. However, despite current controversies regarding true CRC risk categorisation in acromegaly, previous data from the largest published series showed a trend for adenoma and carcinoma formation in the right hemi colon. This is an important observation for many reasons.

Flat adenomas and carcinomas can be difficult to detect by conventional colonoscopy alone, often presenting as subtle mucosal erythema, mucosal pallor, fold convergence, interruption of inominate grooves, air induced deformation, or loss of vascular net pattern. The neoplastic risk for this morphologically distinct group has additionally been shown by many authors to be higher when compared with exophytic polypoid lesions and exhibit a propensity for the right colon. De novo neoplastic lesions and “minute” colorectal cancers are also associated with an increased risk of lymph node metastasis due to early invasion of the submucosal layer. Tada et al found extensive submucosal invasion in a cohort of flat colorectal neoplasms, with Shimoda’s series corroborating these data with submucosal invasion demonstrable in 69% of flat carcinomas compared with only 35% of sessile and broad based polyoid carcinomas.

Morphologically flat and depressed lesions are also known to occur in chronic ulcerative colitis where the need for CRC screening with total colonoscopy and now adjunctive chromoscopy is adopted by many centres. Failure to detect such lesions may in part account for those cases of CRC which occurred in Winawer’s study, despite clearance of all exophytic polyps, and thus stresses the requirement for accurate diagnosis and definitive treatment of these high risk lesions.

Given the lack of standardised and uniform reporting regarding the morphology of colorectal lesions in many of the existing prevalence studies of adenomas and CRC in acromegaly however, at present we can only hypothesis that the high incidence of right hemi colorectal neoplasia may be an indicator of an alternative morphologically distinct lesion such as the flat adenoma and carcinoma with a trend towards a de novo pathogenic sequence.

In our prospective study, 38 patients with acromegaly underwent total colonoscopy by a single endoscopist using the Olympus C240Z magnifying colonoscope. Preparation was with 4 litres of Kleanprep 24 hours prior to the procedure. Panocolonic chromoscopy using 0.5% indigo carmine sprayed onto the colonic mucosa using an Olympus diffusion catheter (CS12890) was applied. Identified lesions were morphologically grouped according to the Japanese Research Society Classification (JRSC). A flat lesion was defined as mucosal change with a flat or rounded surface combined with a height of less than half the diameter of the lesion. High magnification views of all suspected lesions were then obtained and reported according to the modified Kudo criteria. Tissue sampling was performed with cold biopsy or endoscopic mucosal resection following exclusion of a Kudo type V(n)/IIIs invasive crypt pattern which suggests deep submucosal invasion. Mean intubation and extubation times were recorded. Neoplastic change was classified according to the Vienna criteria.

Caecal intubation was achieved in 37/38 (97%) patients with 36/38 (94%) receiving confirmatory terminal ileal biopsies. Males represented 14/37 (37% of the cohort, mean age 64 years (range 40–75)). The mean duration of intubation to the caecum was 16.5 minutes (range 3–51) and extubation (excluding interventional procedures) was 35 minutes (range 20–55). There were no complications.

A total of 28 lesions were identified in 15 patients. Twenty two hyperplastic lesions were identified (79%) of which 17 (77%) were flat (JRSC II). Twenty nine (91%) were located in the left colon and rectum. Of the five adenomas identified, four (80%) were present in the right colon with 4/5 (80%) being of JRSC II morphology. A single adenoma with high grade dysplasia was present in the right colon and was flat with a small area of central depression. No invasive carcinomas were diagnosed. Results are summarised in table 1.

Although the numbers entering this study are small, our results show a clear prevalence for JRSC class II lesions in this select patient group. Although only one adenoma with high grade dysplasia was detected, it was small (5 mm) and was not identified prior to chromoscopic and magnification enhancement, and therefore carries major clinical connotations.

We suggest that further large prospective studies are required to establish the true prevalence of flat and depressed colorectal lesions in acromegaly so that the optimal screening modality and frequency can finally be established. Furthermore, colonoscopists require training in chromoscopic techniques if a higher endoscopically “treatable” lesional frequency is to be detected at a screening level, so as to avoid the high apparent incidence of interval neoplasms.

The editors will decide as whether to also publish it in a future paper issue.
place all of these mucosae in the oesophagus, proximal to the gastro-oesophageal junction. “Primitive oesophageal mucosa” is a ciliated epithelium that develops within about 24 weeks. “Proximal stomach mucosa” is a layer of flat columnar cells containing depressions that correspond to early gland pits distally. “Cardiac mucosa” is composed of foveolar and surface epithelium, forming tubular structures containing no parietal cells. The description of “cardiac mucosa” and figs 2 and 4 show a thin columnar epithelium composed of uniform mucous cells with foveolar pits and rudimentary sac-like structures devoid of any inflammation. Derdoy et al’s “cardiac mucosa” and Park et al’s “transition zone” are identical in appearance. I have never seen this fetal epithelium in any adult patient. The fact that these authors call it “cardiac mucosa” does not make it identical to the more conventional cardiac mucosa seen in adults. The only similarity is that it is a glandular mucosa composed of mucous cells only. It is much thinner than adult cardiac mucosa, it has no inflammation, and its glands are much less developed if present at all.

I would like to propose an alternate explanation for the changes seen in all three papers that provides a better explanation of the data in the papers. The early fetal oesophagus is lined by primitive undifferentiated ciliated columnar epithelium. It begins differentiating into squamous epithelium proximally and gastric mucosa distally. Gastric differentiation is marked by the appearance of true glands containing parietal cells. In the second trimester, the oesophageal squamous epithelium is separated from the differentiating gastric mucosa by a columnar epithelium composed of foregut columnar stem cells forming a flat surface and a foveolar pit. This is uncommitted fetal columnar epithelium. This continues to develop into either squamous epithelium proximally or parietal cell containing gastric mucosa distally. The overall length decreases as fetal age increases (as shown in De Hortogh et al and Derdoy et al’s studies’). With the transition of the development of the lower oesophageal sphincter in early infant life, the physiological gastro-oesophageal junction is defined and the uncommitted columnar foregut epithelium completes its transformation. Squamous in the oesophagus and gastric mucosa with parietal cells distal to the lower oesophageal sphincter. The uncommitted foregut columnar epithelium disappears. The only normal mucosa seen after development is complete are squamous and gastric with parietal cells. This is proven by illustrations that show children with a direct transition of squamous epithelium to gastric mucosa with parietal cells (Chandrasoma et al’s illustrations and fig 2A of Park and colleagues’). The absence of cardiac mucosa in these illustrations is proof that cardiac mucosa is not universally present in children. Adult-type cardiac mucosa is also absent universally in fetuses. The only reason why De Hortogh et al reach the conclusion that it is universally present in fetal life is that they erroneously apply the term “cardiac mucosa” to the uncommitted fetal columnar epithelium that is universally present in fetal life.

Author’s reply

We would like to thank Dr Chandrasoma for his informative reading and kind comments on our work published in Gut. He has also provided the readers with an admirable synthesis of the most recent research on the development of the different mucosal types in the gastro-oesophageal junction region. By means of this letter, we want to reflect on some of his comments.

The quintessence of Dr Chandrasoma’s vision on cardiac mucosa (CM) is that it is a normal structure but not present in the context of gastro-oesophageal reflux disease. The presence of a small length of CM in many “normal” adults could be the result of asymptomatic low level reflux. According to his theory, the “commissural non-glandular late fetal foregut epithelium” (which we call CM in our study) will develop into either oesophageal squamous epithelium or gastric mucosa with parietal cell containing glands. The necessary corollary of his theory is that there can be no such thing as a normal CM. He also puts forward the notion that the presence of CM in some infants might be due to deviation differentiation of the uncommitted epithelium in the context of reflux or other trauma such as nasogastric intubation. Even if this hypothesis is correct, we think that other possibilities should be considered. One possible situation could be the persistence of the uncommitted epithelium with development of a sort of heterotopic CM (analogous to the heterotopic fundic-type mucosa described in the upper third of the oesophagus). Clearly, much more research remains to be done.

Obviously, our work is not completely representative of the development of the gastro-oesophageal junction region throughout gestation. Notably, we need extra specimens from third trimester fetuses. At this moment we are gathering this material for future research. As Dr Chandrasoma himself says, the most important reason for the divergent conclusions of his work and ours are the terminology and interpretation of the data. What we call CM is, in Dr Chandrasoma’s opinion, an uncommitted epithelium devoid of glands. He specifically warns against applying the designation “gland” to the tangentially cut torted ends of the foveolar pits (our fig 2 and fig 4). We believe glands are present in these illustrations. We formed this conclusion both on a purely morphological basis (the gland cells are cuboidal to triangular and contain a centrally located round nucleus) and after histochemical evaluation (the foveolar and pit cells contain a large amount of mostly neutral mucins, whereas the columnar cells for a long time contain only a small amount of mostly acidic mucins). We used the term CM
for this zone interposed between squamous and fundic mucosa because of its morpho-
logical analogy with adult CM (whether normal or abnormal). Its principal character-
istic is the presence of mucus producing glands devoid of parietal cells. We stated that
CM develops during gestation and is present at birth. We do not know what happens with this CM in infants and children. We cannot comment on the identity of adult CM: has it always been there or did it develop through
metaplasia? To prove or disprove Dr Chandrasoma’s theory, evidently much further research has to be done.

Helicobacter pylori infection in Africa and Europe: enigma of host genetics

Helicobacter pylori infection is one of the most common bacterial infections. The prevalence
varies from 25–50% in developed countries to 70–90% in the third world.1 Despite improved
treatment modalities, H pylori related gastro-
intestinal pathology, in common with gas-
tritis, peptic ulcers and consecutive bleeding
events, gastric MALT lymphoma, or carci-
oma, remains a major burden on Western health systems. In the USA, approximately four
million people have active peptic ulcers and about 350,000 new cases are diagnosed
each year. Four times as many duodenal
ulcers as gastric ulcers are diagnosed.2 Epidemiological evidence suggests that both
infection with H pylori and the consecutive development of clinically relevant pathology
are influenced by genetic predisposition as
a fraction of infected are influenced by genetic predisposition as in infection with
Epidemiological evidence suggests that both
gastritis or duodenitis, to erosions and ulcer
disease. Polymorphisms were selected from
the Applied Biosystems “Assay on Demand
service (https://store.appliedbiosystems.com)
and genotyped by Taqman using standard
protocols. Because both polymorphisms were
non-functional single nucleotide polymor-
phisms (rs11914: synonymous T/G exchange
in exon 1, frequency in blood donors 13.5%;
r508914: C/T exchange about 6.5 kb down-
stream of the transcriptional start site, frequency in blood donors 31.3%) a haplotype
case control analysis was performed using
Hapmap3 to assess the association of the
locus with the respective phenotypes. The
markers exhibited a low degree of linkage
disequilibrium (LD) (D’ < 0.174) yielding a
highly informative haplotype analysis of the
locus (frequencies in normal controls: TC
0.386; TT 0.100; GC 0.279; GT 0.335). No
significant association with infection status
or severity of H pylori associated inflamma-
tion was found (table 1).

We conclude that INFGR1 is unlikely to be
involved in the aetiology of H pylori infection
or the development of clinical sequelae in
German Caucasians. This may be due to
aetiological differences between African
and Caucasian individuals, as suggested patho-
physiologically by Mitchell et al, who demon-
strated major differences in the IgG subclass response to H pylori infection in the first and
third world.4 In relation to clinical disease
manifestations, the INFGR1 locus may affect
antibody concentrations but not the clinical
course of H pylori infection in Caucasians.
Alternatively, other immunoregulatory genes
in the vicinity of the INFGR1 locus such as
the interleukin 20 receptor α (200 kb dis-
tance) or MAP kinase 5 (600 kb distance)
could harbour the causative variants.

Platelet activation in patients with irritable bowel syndrome may reflect a subclinical inflammatory response

We read the recent article by Houghton et al and found the results very interesting (Gut 2003;52:663–70). Their observations included higher platelet concentrations of 5-hydroxy-
tryptamine among patients with irritable bowel predominate irritabile bowel syndrome (d-
IBS) compared with controls. It is interesting that a small but significant subgroup of IBS
patients report onset of their symptoms after an episode of acute gastroenteritis and a role of
subclinical inflammatory aetiology has been suggested for the condition.1 The role of
platelets in various inflammatory condi-
tions has previously been demonstrated but their importance in IBS remains unknown.1,2 We recently looked at the possibility of platelet activation in IBS
patients by determining surface expression of the activation markers at baseline and after stimulation. Stimulation involved the use of thrombin receptor activating peptide (TRAP), activation markers P-selectin (CD62) and glycoprotein 53 (CD63), and glycoprotein (GP) receptors GPIb-IX and GPIIb/IIIa, using whole blood flow cytometric analysis (Becton Dickenson Flow Cytometer).1,2 Twenty consecutive IBS patients (18 females), mean age 29 years (20–62), ful-
filling the Rome II criteria (90% d-IBS) and 15 healthy controls (11 females), mean age 28 years (22–49), were included. Raised inflammatory markers, previous bowel dis-
ease or surgery, diverticulosis, and current or past (more than four weeks) use of non-steroidal anti-inflammatory drugs were exclusion criteria.

Standard venepuncture precautions were observed for sample collection and final analysis. A fluorescent isothiocyanate (FITC) conjugated GP Ib specific antibody was used to gate around the platelet population and list mode data on 10 000 platelets acquired. Mean fluorescence intensity (MFI) was used to quantify FITC labelled GPIb/GPIIa and GPIb-IX specific antibody binding. Binding of P-selectin and GP53 to a phycoerythrin-labelled mononuclear antibody was expressed as a percentage of platelets positive for that antibody (% fluorescence). We tested varying strengths of TRAP, ranging from 110 to 650 mm, in five controls and found maximal reactivity of circulating platelets at a concentration of 225 mm (concentration used for activation studies). Differences between groups (p) were assessed using the Mann-Whitney U test for unpaired data. All analyses were performed using the Minitab statistical software and SPSS for Windows.

Baseline expression of P-selectin was significantly increased in the IBS group (median 5.9 (interquartile range (IQR) 4.4–8.9)) compared with healthy controls (median 4.1 (IQR 3.2–5.9)) (p = 0.03), all values representing per cent expression. Baseline expression of GP53 was higher in the IBS group (median 3.0 (IQR 1.9–4.0)) compared with normal controls (median 2.3 (IQR 1.9–2.8)) but failed to reach clinical significance. TRAP stimulation resulted in increased expression of P-selectin and GP53 in both groups. Glycoprotein reactivity post stimulation was significantly lower in the IBS group compared with normal controls (p=0.05).

The numbers of GPIb/IIa and GPIb-IX receptor sites on the platelet surface for each group were calculated using a calibration curve where MFI and the corresponding number of antibody sites of multiple bead populations were plotted using a log log scale. The results in the two groups were comparable.

In IBS patients with normal routine inflammatory markers, we demonstrated a significant increase in surface expression of baseline and P-selectin. The observed changes in baseline and reactive expression of platelet activation markers may support the theory of an ongoing subclinical inflammatory process in IBS. Reduced glycoprotein reactivity following TRAP stimulation in IBS may possibly signify a continuous low level platelet activation and degranulation with consequent platelet “exhaustion” and reduced expression of antigens. Precise interpretation of our results remains unclear due to the small number of included patients. Future studies involving a wider IBS population with possible subdivision based on the various disease characteristics, including determination of the possible disease triggering event, particularly a past history of gastroenteritis, may help to further clarify these observations.

CORRECTIONS

Two errors have been noted in the paper by Cj Hawkay et al in the June issue (Incidence of gastrudodenal ulcers in patients with rheumatoid arthritis after 12 weeks of rofecoxib, naproxen, or placebo: a multicentre, randomised, double blind study. Gut 2003;52:820–6). On page 822, the lower 95% CI for the difference between rofecoxib and placebo (4.05), is given as 93.37 rather than 3.37. Also, in the key to fig 2, the dose of rofecoxib is given as 500 mg instead of 50 mg.

In the letter by Siveke et al (Gut 2003;52:1531) the author list was ordered incorrectly as JT Siveke, JF Overath and C Herberholz. The correct order for the listing of authors should have been JT Siveke, C Herberholz and JF Ovolaczky. This was due to a technical error for which the journal apologises.

NOTICES

British Society of Gastroenterology
Paul Brown Travel Fellowships

The Paul Brown Travel Fellowships are awarded by the Endoscopy Committee of the BSG. They intend to assist trainee gastroenterologists and established consultants in visits to units outside the United Kingdom for specialist experience and training in endoscopy.

Specialist registrars who have not achieved their CCST are expected to have the approval of their Postgraduate Dean and their Regional Training Director when they apply for a Travel Fellowship. Applicants are expected to provide confirmation that they have been accepted for training in the unit that they wish to visit.

Successful applicants will be expected to provide a brief written report to the Endoscopy Committee of the outcome of their visit.

Application forms are available from the British Society of Gastroenterology Office, 3 St Andrew’s Place, London NW1 4LB. Email: bsg@mailbox.ulc. ac.uk

Hong Kong-Shanghai International Liver Congress 2004

This conference will be held on 14–17 February 2004 in Hong Kong. The topic of the conference is “Liver Diseases in the Post-Genomic Era”. Further details: Ms Kristie Leung, Room 102–105 School of General Nursing, Queen Mary Hospital, 102 Pokfulam Road, Hong Kong. Tel: +852 2818 4300/8101 2442; fax: +852 2818 4030; email: kristieleung@hepa2004.org; website: www.hepa2004.org

PET/CT and SPECT/CT Imaging in Medical, Radiation, Surgical and Nuclear Oncology

This continuing medical education programme will take place on 19–20 March 2004 at Johns Hopkins University School of Medicine, Baltimore, Maryland, USA. Further details: Office of Continuing Medical Education, Johns Hopkins University School of Medicine, Turner 20, 720 Rutland Avenue, Baltimore, Maryland 21205-2195. • Deadline for early registration 10 February 2004

Second Sheffield Multi-Disciplinary Colorectal Meeting

There will be a multi-disciplinary symposium for surgeons, physicians, radiologists and specialist nurses on 9 January 2004. The faculty includes: Wendy Atkin—St Mark’s (London), Professor Jonathan Rhodes—University of Liverpool, Professor John Schofield—Nottingham, Dr S Taylor—St Mark’s Hospital, Mr Andrew Shorthouse—Sheffield, Dr Stewart Riley—Sheffield, and Karen Smith—Nurse Endoscopist at Sheffield. The Second Sheffield Multi-Disciplinary Colorectal Meeting takes place between 10am and 5pm at the Postgraduate Centre, Northern General Hospital, Sheffield. The registration fee is £25. For further details, please contact: Anne Smedley, Secretary to Mr AJ Shorthouse, Royal Hallamshire Hospital, Glossop Road, Sheffield, S19 2JF.
