Severe polyneuropathy complicating active Crohn’s disease: rapid response to Infliximab

Treatment with a chimeric antitumour necrosis factor (TNF) antibody (Infliximab) has been shown to be highly efficient for patients with steroid refractory Crohn’s disease (CD).

However, the mechanism of action remains with steroid refractory Crohn’s disease (CD).

Recently, a favourable response to Infliximab treatment was demonstrated in some diseases complicating active CD such as acute idiopathic pancreatitis. We report a case of a middle aged female with CD that developed an aggressive form of polyneuropathy resistant to corticosteroids.

A 55 year old White female, weighting 68 kg, presented with exacerbation of CD (CDAI activity index (CDAI) >450) associated with potentially life threatening symptoms of chronic corticosteroid abuse. Immunosuppressive therapy with azathioprine was rapidly stopped for gastric intolerance. Neuropathy was characterised by arthritis, myalgias, and functional impotence. She had been suffering from refractory severe CD involving the ileum and right colon for 10 weeks. She was therefore under treatment with cyclosporin whilst pregnant.

We report a case (submitted for publication) of a woman with fulminant ulcerative colitis in the 29th week of pregnancy. Her disease was refractory to steroids, but she refused to have cyclosporin whilst pregnant. She therefore underwent an emergency Caesarean section and was given intravenous cyclosporin post-operatively. After 48 hours of treatment she developed severe hypertension with hypertensive encephalopathy and seizures. Although cyclosporin has been considered to be safe for both mother and foetus, we would like to highlight concerns that it is associated with potentially life threatening side effects. As a result, patients must be counselled thoroughly about the potential morbidity associated with this treatment and monitored closely. We agree with Dr Alstead in that cyclosporin should be used with extreme caution in pregnancy and the postnatal period.

Caution with the use of cyclosporin in pregnancy

We read the article by Alstead and Nelson-Piercy with great interest.

We report a case (submitted for publication) of a woman with fulminant ulcerative colitis in the 29th week of pregnancy. Her disease was refractory to steroids, but she refused to have cyclosporin whilst pregnant. She therefore underwent an emergency Caesarean section and was given intravenous cyclosporin post-operatively. After 48 hours of treatment she developed severe hypertension with hypertensive encephalopathy and seizures. Although cyclosporin has been considered to be safe for both mother and foetus, we would like to highlight concerns that it is associated with potentially life threatening side effects. As a result, patients must be counselled thoroughly about the potential morbidity associated with this treatment and monitored closely. We agree with Dr Alstead in that cyclosporin should be used with extreme caution in pregnancy and the postnatal period.

An infusion of 3 mg/kg Infliximab (Remicade; Schering-Plough SpA) was given at weeks 0, 2, and 6. Infliximab infusions at eight week intervals were administered. Infliximab was well tolerated and no side effects were recorded. Arthralgias, myalgias, and functional impotence of the right arm and leg progressively improved after the first Infliximab infusion. Muscle atrophy of the right hand improved dramatically two weeks later. Electromyography performed at week 22 after the start of therapy was normal. CDAI score is <150 at this time. Sign and symptoms of chronic corticosteroid therapy rapidly disappeared.

In conclusion, Infliximab may be a suitable therapeutic option in patients with rare extraintestinal manifestations of CD such as severe polyneuropathy not responding to conventional therapy.

Coeliac disease: is case finding the correct ethical and logistical approach?

I read with interest the debate pertaining to screening for coeliac disease (CD). Although one can argue that CD fulfils the tenets of any screening programme, however, we do not know the natural history of screen detected patients with CD.

Logistically when would we decide to screen—at what age and how often thereafter? Serological markers may be highly sensitive and specific but the value of these tests decrease when they are used in the general population.

Although the investigational process for population screening and case finding may be the same, there is an important ethical difference between them. If a patient seeks medical help then the physician is attempting to diagnose the underlying condition (for example: patients with CD who present with symptoms of irritable bowel syndrome). This would be classified as case finding and clearly it is the patient who has initiated the consultation and in some sense is consenting for investigation. Conversely, individuals (who are not patients) found to have CD through screening programmes, may have considered themselves as “well” and it is the physician or healthcare system that is identifying them as potentially ill.

We recently performed a primary care based cross sectional study using immunoglobulins, IgA/IgG antigliadin antibodies and endomyosal antibodies to initially recognise CD. 1200 volunteers were recruited from January 1999 to June 2001 from 5 general practices in South Yorkshire, UK. Any participant with a positive IgA antigliadin antibody, positive endomysial antibody or only IgG antigliadin antibody in the presence of IgA deficiency was offered a small bowel biopsy to confirm the diagnosis of CD. Twelve new cases of CD were diagnosed from 1200 samples. The prevalence of CD in this primary care population sample is 1% (95% CI 0.4–1.3%). In this screening study, 9/12 diagnosed cases of CD ultimately had symptoms which could be attributed to CD (for example, anaemia or subtle gastrointestinal symptoms). We, and others have demonstrated a delay in the diagnosis of CD—surely the important change in our clinical practice (both in primary and secondary care) is to have a low threshold for case finding. “If you look for CD you will find it.”

Severe polyneuropathy complicating active Crohn’s disease: rapid response to Infliximab

Treatment with a chimeric antitumour necrosis factor (TNF) antibody (Infliximab) has been shown to be highly efficient for patients with steroid refractory Crohn’s disease (CD).

Recently, a favourable response to Infliximab treatment was demonstrated in some diseases complicating active CD such as acute idiopathic pancreatitis. We report a case of a middle aged female with CD that developed an aggressive form of polyneuropathy resistant to corticosteroids.

A 55 year old White female, weighting 68 kg, presented with exacerbation of CD (CDAI activity index (CDAI) >450) associated with an aggressive form of polyneuropathy involving the right arm and leg with arthralgias, myalgias, and functional impotence. She had been suffering from refractory severe CD involving the ileum and right colon for 10 years and she was taking oral corticosteroids for two years continually with signs and symptoms of chronic corticosteroid abuse. Immunosuppressive therapy with azathioprine was rapidly stopped for gastric intolerance. Neuropathy was characterised by arthritis, myalgias, and functional impotence of the right arm and leg. Severe muscle atrophy of the right arm was evident and deascamation was very difficult. Therapy with folate, vitamin B12, and vitamin B6 was ineffective. A magnetic resonance scan of the cranium and spinal cord excluded central, optic nerve, and spinal cord demyelinating lesions. Electromyography showed demyelinating neuropathy involving the right and left external popliteus ischiatic nerve, a mixed (motor and sensory) neuropathy involving the right and left radial nerve, and an axonal neuropathy involving the right ulnar and medial nerve. Other conditions such as polyarteritis nodosa, Wegener’s granulomatosis, primary mixed cryoglobulinaemia, rheumatoid arthritis, systemic lupus erythematosus, or sarcoidosis had been excluded.
very large study conducted by an expert team in this field were that mean age at diagnosis was higher in men (p<0.01), mean FHN size was smaller (p<0.001), and more men were performed (p<0.001) in men (n=18) than in women (n=216). Interestingly, perhaps because of the relatively small number of men (although very large in terms of the rare occurrence of FHN in men), no cases of multiple FHN were noted in the male population. We report here a case of multiple FHN in a 74 year old patient with a biopsy proven prostatic cancer. This patient had not received any treatment. He was referred to our liver unit in March 2001 for evaluation of multiple liver masses discovered on abdominul ultrasonography during the staging of his cancer. Bone scintigraphy disclosed no metastases. Liver biochemical was normal except for a mild increase in gamma glutamyl transferase activity. Prothrombin index was 100%. Serological search for hepatitis B or hepatitis C virus infection was negative. Genetic (haemochromatosis, alpha 1 antitrypsin deficiency) and autoimmune liver diseases were carefully excluded, and alcohol consumption was below 10 g/day. Upper gastrointestinal endoscopy and colonoscopy showed normal. Tumour markers of malignant primary or secondary liver lesions were within the normal range. Liver Doppler ultrasonography disclosed multiple heterogeneous lesions with a hyperechoic pattern without an arterial signal. Abdominal tomodensitometry before and after contrast enhancement showed multiple lesions with rapid contrast enhancement during the arterial phase. The largest lesion was located between the left liver and segment IV and measured 75 mm.

Because there was no magnetic resonance imaging (MRI) in our centre, ultrasound guided liver biopsy in both tumoral and non-tumoral areas was performed. The diagnosis of typical FHN was made in several of the lesions whereas non-tumoral liver was normal.

The patient received hormonal treatment and measured 75 mm. A large study conducted by an expert team in this field were that mean age at diagnosis was higher in men (p<0.01), mean FHN size was smaller (p<0.001), and more men were performed (p<0.001) in men (n=18) than in women (n=216). Colonoscopic screening recommended by Jenkins and Fairclough should be seriously questioned.

Authors’ reply
We thank Dr Renehan and colleagues for their comments on our data, which they have also made previously. We do not claim that our data are perfect in all respects but it seems to us, on the basis of the data we have collected in our own series and that of other groups, that patients with acromegaly should be regarded as having a significantly increased risk of colorectal neoplasia. The two contrary studies referred to by Renehan et al are his own and that of one other author who relied upon retrospective data acquired more than 50 years ago. These data and those from the population-based studies preferred by Renehan suffer from flaws of their own. The morbidity associated with acromegaly has changed in the last 25 years, probably related to the increased survival associated with aggressive and effective treatment of the cardiovascular and metabolic complications of the disease. Our data and those of others show that the prevalence of colon neoplasia in acromegaly is age dependent. Thus it is only now that patients are surviving long enough to develop this complication, and valid comparative data must therefore be acquired contemporaneously, to take account of the changing pattern of morbidity associated with increased longevity.

We are aware of at least 12 other prospective studies evaluating colonoscopic screening in acromegaly in addition to our original report from St Bartholomew’s Hospital. These include one by Renehan et al in which they reported three asymptomatic patients in whom a cancer was detected. Among such studies the optimum comparison must be simultaneous screening of asymptomatic non-acromegaly matched controls and a combined comparison of the data from all series using these control groups, none of which involved mixed race US populations, gives a relative risk of colon cancer in acromegaly of 13.4. We therefore feel it is prudent to accept the evidence of an increased risk of colon cancer, derived from these clinical observations rather than from theoretical calculations, and to screen acromegalic patients systematically until the current hypothesis is confirmed or refuted. The rarity of acromegaly means that the increase in workload for the majority of individual endoscopy units is likely to be minimal.

New imaging techniques: promise or passe
I read with great interest the article by Egger and colleagues (Gut 2003;52:18–23) evaluating laser induced fluorescence endoscopy (LIFE) and methylene blue (MB) directed biopsies for detection of dysplasia in Barrett’s oesophagus. As the authors point out, there have been no fully published studies to date on this much talked about procedure. The authors found that LIFE and MB had limited accuracy, as did standard random biopsy. Although LIFE and MB detected a total of five cases of high grade dysplasia and 11 cases of low grade dysplasia on 4QB, they concluded that these methods are “not capable of increasing the diagnostic accuracy or replacing standard four quadrant biopsies”.

How could these data lead to this conclusion? The authors discount all but one high grade and seven low grade lesions detected by LIFE or MB because they were “within 4QB protocol”. It was assumed by the authors that these sites would have been biopsied by random techniques had it not already been sampled with AF or MB. Given that the biopsies were standard 7 mm forceps, that dysplasia can be very focally distributed, and the area included within the 4QB covers two linear centimetres, it is difficult to assume that this exact site would have been biopsied with a random technique. This assumption, if incorrect, would result in underestimation of the value of LIFE or MB.

In addition, the authors further discounted the one remaining high grade dysplasia site and four more low grade sites because they occurred in patients with known cancer who presumably would be treated for the cancer regardless. There is little doubt that detection of low or even high grade dysplasia has little relevance if a cancer is already known. The main group of patients where LIFE, MB, and other advanced techniques should be applied are those with neither histologically evident tumours and cancer. Discounting LIFE and MB for this reason may further underestimate its value.

If we do not discount these cases then LIFE and MB appear to complement 4QB for the detection of dysplasia, with each technique being better at detecting dysplastic sites that the other missed.

I agree that LIFE and MB remain controversial and applaud the authors for publication of this study. Given the limitations of the study however, it may be premature to proclaim these techniques incapable. More well conducted studies are clearly needed. The field of imaging technologies is also evolving rapidly and new and better techniques are constantly on the near horizon.

Transient ischaemic colitis following an aeroplane flight
We read with interest the report of Butcher and colleagues (Gut 2002;51:746–7) of two cases of transient ischaemic colitis following an aeroplane flight. This report represents more evidence supporting the suggestion of a possible important role of acquired and hereditary thrombotic risk factors in the pathogenesis of ischaemic colitis.1 However, the largest study to date concerning these factors in patients with ischaemic colitis was not mentioned in the study. Moreover, the reported patients may also have other acquired or inherited thrombophilic disorders which were not evaluated. Lipoprotein (a), anticoagulant and homocysteine levels were not evaluated. Although the aeroplane flight could be the most important risk factor in these cases, the rather incomplete thrombophilic screening does not permit us to conclude that it was “the only potential risk factor”. It is known that deep vein thrombosis (mainly symptomatic) may occur in up to 10% of long haul airline travellers.1 In contrast, hypercoagulable status is commonly believed to play a role in ischaemic colitis, leading to the development of thrombotic occlusion of the small vessels supplying the colon. In a recent study of comprehensive thrombophilic screening in patients with an established diagnosis of ischaemic colitis, we found the prevalence of acquired and hereditary thrombotic risk factors significantly higher compared with the prevalence of these factors in matched inflammatory and healthy controls.1 A thrombophilic tendency was demonstrated in the majority of patients and the most significant associations were with antithromophilic antibodies and with the factor V Leiden mutation. Moreover, we recently found a high frequency of protein Z deficiency in patients with ischaemic colitis (unpublished data). Based on the recent data of the association of protein Z deficiency mainly with arterial thrombosis,1 protein Z deficiency may be involved in the development of the disease in a subgroup of patients by causing thrombosis in the small mesenteric arteries.

Transient ischaemic colitis is considered the result of localised non-occlusive ischaemia of the small arteries. In contrast, the prevalence of hypercoagulable states suggests a possible role of

venous obstruction. It is possible that future identification of subgroups in ischaemic colitis patients with sophisticated imaging techniques could distinguish cases with arterial or venous ischaemia.

In conclusion, we suggest that the mechanism of ischaemic colitis is multifactorial. Acquired and genetic factors may interact leading to disease manifestation. Arrhythmia and embolic conditions, oral contraceptives, and other medications, as well long haul flights probably play a role in genetically predisposed individuals in the disease pathogenesis.

BOOK REVIEWS

Surgery of the Liver, Bile Ducts and Pancreas in Children

This excellent volume builds on the success of the first edition published a decade ago by the senior editor (ERH). Inevitably it is bigger, and, yes, better too. The contributors, drawn from across the world, have been chosen for their expertise and this is apparent in their respective chapters. A major beneficial innovation is inclusion of an editor and other contributors from the USA; sadly, for an inherently English book, English spelling has been sacrificed in the process.

All chapters have been rewritten in response to the significant developments in hepatobiliary surgery over the past decade—for example, in the anatomy of the liver and in liver transplantation (now up from 14 to 98 pages). The chapter on “portosystemic shunt surgery” has given way to “surgery for portal hypertension”, reflecting the development of alternative strategies for this condition. As before, detailed and informative chapters on anatomy, physiology, and preoperative management complement the core “surgical” chapters, and there are new chapters on embolology, anaesthesia and perioperative care, nutrition, and the psychosocial aspects of childhood liver disease, which will be of interest to gastroenterologists and surgeons alike. Another innovation is the inclusion in a section on “surgical” paediatric pancreatic disorders, including chapters on embryology and anatomy; this is a logical development that enhances the value of this volume.

The scientific standard is high throughout the book. Each of the topics has been well researched by its author and (with only one exception), chapters are well referenced. Of course one can find omissions but these are minor and very infrequent. The text is easy to read and the editors have ensured that the content is clinically relevant. Each chapter concludes with a useful table of annotated key references, and in some chapters a recommended management strategy is summarised in a box. The book is liberally illustrated with line drawings and both black and white and colour figures, which generally are informative and clearly reproduced. The index is good; I was able, without difficulty, to locate a variety of topics. Overall, the quality of the production is excellent, with very few typographical errors. Although this is a comprehensive book, it is not a large tome, but is comfortable and easy to read.

This book will serve as an invaluable resource for gastroenterologists, paediatricians, surgeons, nurses, and others involved in the surgical care of children with liver, biliary, or pancreatic disorders, whether at a specialist children’s centre or a district hospital, and will appeal to trainees, whose exposure these days to complex hepatobiliary surgery is limited. In addition, gastroenterologists and surgeons treating the increasing number of adults with disorders of childhood will find this book a most helpful companion.

D Lloyd

Gastrointestinal Mucosal Repair and Experimental Therapeutics

This book is a worthy addition to the Frontiers of Gastrointestinal Research series that focuses on specialised gastrointestinal research topics. This volume is the 25th of the series and highlights areas of current and emerging interest to investigators in the area of gastrointestinal mucosal injury, repair, and therapeutics. The book is not a compilation of talks given at a conference but rather an honest attempt to inform about specialized research areas within that broad field. It has been a number of years since anyone has gathered the information for this book. The editors have intentionally chosen to invite experts to write on their specialised subjects. The emphasis of the book is on the use of experimental cell culture and animal models and, therefore, will be of most use to basic researchers. The book is divided into three broad sections, covering epithelial restitution, mucosal repair and healing, and experimental therapeutics.

The chapter authors have taken care to summarise what is known and what remains to be investigated. Several of the chapters provide reviews of a particular area such as summarising those on angiogenesis, the diacylglycerol/protein kinase C pathway, nitric oxide and its regulation, the roles of cyclooxygenase inhibitors, and the involvement of prostaglandin receptor–receptor interactions in the gastrointestinal tract. Other chapters contain useful methodology regarding animal models and experimental techniques such as physical stress and strain. The chapters dealing with cytokines and Helicobacter pylori infection are brief, but these subjects are adequately covered elsewhere in numerous reviews.

The book will serve as an invaluable resource for research newcomers and veterans alike in the field.

E J Dial

The Handbook of Clinical Trials and Other Research

Clinicians are notorious for embarking upon research without a full understanding of methodology. Perhaps in the past clinical journals were guilty of publishing papers without being sufficiently critical. No doubt this was a byproduct of well meaning referring clinicians who were themselves hamstrung methodologically and, lacking insight. In the new world of publications, the research design has to be explicit, well laid out, and sufficiently robust to support the research reported. Most doctors have had little or no training in research methods, despite having completed an MD. This might be one reason why it is becoming increasingly difficult for even research experienced clinicians to initiate new projects. Indeed, there is a question mark as to whether research can now be done by service based clinicians or whether, because of the newer strictures and disciplines, this should be left to the professional researcher. Perhaps the answer is that clinicians ought to have access to experts who can not only guide them but see them through the entire project. Some have questioned whether clinical research is still possible, the answer, even if only in hope, is yes, but this will require a greater familiarity with research methodology, the patience to plan thoughtfully, and with experienced clinicians.

This handbook provides definitions and contemporary examples. It provides recent references from major journals and is well illustrated. It contains material beyond explanations of research terminology and methodology including the new requirements for the Research Ethics Committees, and the EU Clinical Trials directive. This handbook is fast moving; in the UK there is a single electronic ethics application form now with new rules regarding consent for multicentre

Hepatology Principles and Practice
E Kuntz, H-D Kuntz. Berlin: Springer Verlag. colour, pp 825. ISBN 3540 42161 0

“You have a very large parcel”, Zeinab, my secretary said breathlessly as she struggled up from the post room with a copy of this enormous book. It seemed all the heavier as I lagged it around the London bus network from the wilds of East Acton on my way home and then back to work several times. Contained in a reinforced Harrod’s bag, which was the only thing I could find that was strong enough to hold it while I elobowed my way through the myriads of commuters that were forced to travel by bus in lieu of the non-existent Central line, I felt my back pain had returned with a vengeance and did not know whether to take up weight training (where the book would come in handy) or admit defeat and sue the authors for damages. However, sanity soon prevailed and I soon became engrossed in this weighty tome.

At first glance, one could say that another comprehensive book on hepatology is really not needed, given all the other titles on the market. However, it turns out that this 2002 English edition of the original German “Praktische Hepatologie”, published in 1998, has been updated and was a labour of love by Erwin Kuntz whose son, Hans-Dieter, died before the book could be finished. My schoolboy German is not up to the original edition but this has become a bible in Germany and the current version is welcome, despite the fact that a lot of the English is somewhat awkward with curious turns of phrase. Examples of this include “MRT”, rather than MRI, which is irritating, and “lethality”, rather than mortality, which interrupts one’s reading pattern. However, there are some very nice things about the book. It has an interesting section on the history of hepatology, perhaps written from a German perspective, since the late Dame Sheila Sherlock may have had a different take on events. Otherwise, there are 40 chapters, which are essentially written as a “hairdresser’s guide” to being a hepatologist, with nicely illustrated sections on anatomy (termed “morphology”) and biochemistry, before launching into sections on clinical findings and laboratory tests which are comprehensive and well written. There are unusually detailed sections on how to perform liver biopsies and a practical manual on ultrasound (termed “sonography”), the likes of which I have not found in books from the English speaking world, probably because ultrasound is the domain of gastroenterologists in Germany but the presence of radiologists in the UK. Nevertheless, this level of detail is useful for hepatology/gastroenterology SPTs who would like to interpret scans better but feel inhibited asking their local x-ray department for fear of looking stupid. However, the section on CT is scanty and on MRI (“MRT”) is almost non-existent by comparison. It is a shame that the chapter on cognitive testing and the investigations of the neurological sequelae of liver disease does not contain detail on newer psychometric tests and technology such as MR spectroscopy, given the wealth of expertise on hepatic encephalopathy that currently exists in Germany. Chapters on the complications of chronic liver disease are well set out and those on liver abscesses, bacterial, parasitic, and fungal (“myotic”) liver disease are useful.

The question of who may actually buy this book looms large. It is too big and too costly for any individual junior doctor who might be interested in this “user’s guide” approach that the book adopts. However, I would have thought given the fact that the format of its main competitor, the Sherlock book, is looking dated by comparison and that other books are not as visually inviting, the Kuntz tome would find a home in most hospital libraries, if the local gastroenterology department is feeling flush, then on the shelf of the departmental secretary for reference use by all who pass by. For what it is worth, Zeinab has decided to check the strength of her newly reinforced shelves by clearing a space in anticipation of her copy.
