Transactivation of the epidermal growth factor receptor by cag+ Helicobacter pylori induces upregulation of the early growth response gene Egr-1 in gastric epithelial cells

S Keates, A C Keates, S Nath, R M Peek Jr, C P Kelly

Background and aims: Helicobacter pylori, in particular cytotoxin associated gene (cag)+ strains, have been shown to enhance gastric epithelial cell proliferation in vivo, an effect that likely contributes to gastric carcinogenesis. Early growth response gene 1 (Egr-1) is a crucial regulator of cell growth, differentiation, and survival, which is known to play a role in carcinogenesis and cancer progression. The aims of this study were to: (1) examine whether H pylori could upregulate Egr-1 in gastric epithelial cell lines; (2) determine whether there was a differential response to infection with different strains; and (3) examine the role of the cag pathogenicity island in this process; and (4) elucidate the molecular mechanisms leading to Egr-1 upregulation.

Methods and results: We found that infection of AGS cells with cag+ H pylori resulted in a rapid (1–2 hours) but transient increase in Egr-1 mRNA and protein levels whereas coculture with cag– isolates did not elicit this response. Furthermore, two independent cagE– isogenic mutants of H pylori also demonstrated impaired ability to upregulate Egr-1. Upregulation of Egr-1 protein was inhibited by the extracellular regulated kinase (ERK)1/2 inhibitor PD98059 and overexpression of dominant negative MEK1 downregulated Egr-1 luciferase reporter gene activity. Treatment of AGS cells with the epidermal growth factor receptor (EGFR) kinase inhibitors PD153035 and AG1478 resulted in a reduction in H pylori mediated Egr-1 upregulation, demonstrating that EGFR transactivation plays a role in this early cellular process.

Conclusions: Our findings show that cag+ H pylori cause rapid induction of Egr-1 in gastric epithelial cells which may contribute to H pylori mediated pathogenesis.

Helicobacter pylori is a gastric pathogen that infects over half the world’s population. This Gram negative bacterium colonises the epithelial layer of the stomach and induces a state of chronic inflammation that can lead to the development of life threatening diseases, including gastric and duodenal ulceration and distal gastric adenocarcinoma. The interaction between H pylori and gastric epithelial cells results in activation of multiple signalling cascades such as mitogen activated protein kinase (MAP) pathways, and also activation of transcription factors such as nuclear factor κB and AP-1 which have been shown to be important in regulating the host inflammatory response.

H pylori strains can be broadly divided into cytotoxin associated gene (cag)+ strains and cag– strains, depending on whether or not they possess a 40 kb region of genes known as the cag pathogenicity island (cag PAI). The genes that comprise the cag PAI encode for a type IV secretion system which acts as a molecular syringe to deliver the immunodominant CagA protein into the cytosol of the host cell. In addition to this delivery of peptidoglycan to host cells by the bacterial type IV secretion system, it has also been demonstrated that H pylori strains that possess the cag PAI have been found to induce more severe gastritis and augment the risk of developing peptic ulcer disease and distal gastric cancer. Furthermore, it has been shown that H pylori cag+ strains selectively enhance proliferation and attenuate apoptosis of epithelial cells in vivo compared with cag– strains. Differences have also been observed in the abilities of cag+ and cag– H pylori strains to activate various signalling cascades in infected gastric epithelial cell lines.

Early growth response gene 1 (Egr-1) is a 80–82 kDa transcription factor also known as zif268, NGFI-A, Krox24, and TIS8. It is rapidly and transiently induced by a number of extracellular stimuli, including growth factors, cytokines, and injury related stimuli. Egr-1 is functionally implicated in numerous critical biological processes, including inflammation, cell proliferation, cell differentiation, vascular wound response, and cancer progression. Interestingly, Egr-1 levels have been found to be elevated in gastric cancer tissues and it has been suggested that Egr-1 may play an important role in carcinogenesis and cancer progression in the stomach.

In this study, we set out to examine whether H pylori could induce an increase in Egr-1 in gastric epithelial cells and the mechanism regulating this effect. We also examined whether there were differences between strains in their ability to upregulate Egr-1 and, in particular, to assay the importance of the cag PAI in this process.

Abbreviations: Egr-1, early growth response gene 1; EGFR, epidermal growth factor receptor; ERK, extracellular regulated kinases; MAP kinases, mitogen activated protein kinases; PAI, pathogenicity island; cag, cytotoxin associated genes; PMA, phorbol-12-myristate-13-acetate; MOI, multiplicity of infection; GAPDH, glyceraldehyde-3-phosphate dehydrogenase; PCR, polymerase chain reaction; EMSA, electrophoretic mobility shift assay; JNK, c-Jun N-terminal kinase.
MATERIALS AND METHODS

Cell culture and reagents

AGS gastric epithelial cells (American Type Culture Collection, Rockville, Maryland, USA) were maintained as previously described. Cell culture experiments were carried out using 6, 12, or 24 well or 100 mm polypropylene tissue culture plates (Corning Costar, Cambridge, Massachusetts, USA). All experiments were carried out using confluent monolayers unless otherwise stated. Phorbol-12-myristate-13-acetate (PMA) and pharmacological inhibitors AG1478, SB203580, PD98059, PD153035, SP600125, and actinomycin D were all obtained from Calbiochem (La Jolla, California, USA).

H. pylori strains, clinical isolates, and isogenic mutants

H. pylori were cultured and prepared as previously described. Unless otherwise stated, experiments were performed using the cagA+/vacA+ H. pylori strain 43504 (American Type Culture Collection). Isogenic H. pylori mutants lacking the cagE or cagA gene were studied together with their parental cag+ toxigenic wild-type strain 60190. A second set of H. pylori isogenic mutants lacking either the cagE or cagA gene were also studied along with their parental cag+ toxigenic wild-type strain J166. Mutants and clinical isolates 34J (cag−, vacA s1a m2), J338 (cag+, vacA s1a m2), J368 (cag−, vacA s2 m2), 107A (cag−, vacA s2 m2), and J166 (cag+, vacA s1b m1) were obtained from Vanderbilt University Campylobacter and Helicobacter Laboratory (Nashville, Tennessee, USA). All clinical isolates were obtained from patients with gastritis except for J166 which was from a patient with duodenal ulcer disease.

Western blotting

AGS cells were grown on 12 well plates and maintained in serum free medium for 24 hours prior to the experiment to avoid cell stimulation by serum growth factors. H. pylori were added in serum free medium and cocultured for varying lengths of time (multiplicity of infection (MOI) 20:1; bacteria:cell). At the end of the experiment, monolayers were washed three times with phosphate buffered saline and lysed. Samples were loaded onto an 8% sodium dodecyl sulphate-polyacrylamide gel and transferred to nitrocellulose membranes (Bio-rad, Hercules, California, USA). Western blotting analysis was carried out using Egr-1 and extra-cellular regulated kinase (ERK)2 antibodies from Santa Cruz Biotechnology (St Louis, Missouri, USA), and a phospho-specific-ERK1/2 (Cell Signaling Biotechnology, Beverly, Massachusetts, USA).

Analysis of Egr-1 and GAPDH mRNA levels using real time reverse transcription-PCR (Taqman assay)

Total RNA was isolated from AGS cells using guanidine isothiocyanate-phenol-chloroform extraction. RNA (1 μg) was reversed transcribed using random hexamer primers and Moloney murine leukaemia virus transcriptase, as previously described, and the resulting cDNA was stored at −80°C.

Egr-1 and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) mRNA levels were determined using real time polymerase chain reaction (PCR) with a GeneAmp 5700 sequence detection system (ABI/Perkin-Elmer). cDNA was incubated for two minutes at 50°C, denatured for 10 minutes at 95°C, and then subjected to 40 cycles of annealing at 55°C for 20 seconds, extension at 60°C for one minute, followed by denaturation at 95°C for 15 seconds. The gene specific primers used were Egr-1 sense primer, 5’ CCC GGT CCG ATC CTT T 3’; Egr-1 antisense primer, 5’ CAG CAT CAT CTC CTC CAG GTT 3’; GAPDH sense primer, 5’ GAC CAC AGT CCA TGC CAT CA 3’; and GAPDH antisense primer, 5’ CAT CAC GCC AGA GTT TCC C 3’. To detect amplicons generated using the gene specific primers, dual labelled fluorogenic (Taqman) probes containing TAMRA (at the 5’ end) and FAM (at the 3’ end) were synthesised (Sigma-Genosys, The Woodlands, Texas, USA). The Taqman probes used were: Egr-1, 5’ ACT CGC CCA TGA TGC ACT ACC C 3’ and GAPDH, 5’ ACC CAG AAG ACT GTG GAT GGC CCC 3’. Egr-1 levels in each sample were normalised to GAPDH expression, and the relative change in mRNA level was expressed as fold induction compared with untreated cells using the −ΔΔCT method.

Electrophoretic mobility shift assay (EMSA)

Confluent 100 mm plates of AGS cells were exposed to H. pylori over a four hour time course and nuclear extracts were prepared as previously described. Double stranded oligonucleotides containing consensus binding sites for Egr-1 were obtained commercially (Santa Cruz Biotechnology). The oligonucleotides were end labelled using T4 polynucleotide kinase in the presence of [α-32P]ATP and then purified on a Sephadex G-25 spin column (Boehringer Mannheim, Indianapolis, Indiana, USA). Binding reactions (20 μl) contained 0.1 ng (~15 000 cpm) of double stranded probe, 5–12 μg of extracted protein, 2 μg of poly(dI-dC) (Pharmacia, Piscataway, New Jersey, USA), 10 mmol/l 2-ME, and 1% Ficoll. After first incubating the protein extracts for 10 minutes at room temperature, the radiolabelled probe was added. After an additional 30 minutes at room temperature, reaction mixtures were then loaded onto a non-denaturing 4.5% polyacrylamide gel and transferred to nitrocellulose membranes (Bio-rad, Hercules, California, USA). Electrophoretic mobility shift assay (EMSA) was carried out using Egr-1 and extra-cellular regulated kinase (ERK)2 antibodies from Santa Cruz Biotechnology (California, USA), an actin antibody from Sigma-Aldrich (St Louis, Missouri, USA), and a phospho-specific-ERK1/2 (Cell Signaling Biotechnology, Beverly, Massachusetts, USA).

Transient transfection of AGS cells with an Egr-1 luciferase reporter

AGS cells were transfected using Transfast (Promega, Madison, Wisconsin, USA) according to the manufacturer’s instructions. Briefly, cells were plated 24 hours before transfection at a density of 3×10^5/well on a 12 well tissue culture dish (Corning Costar). The next day cells were transfected with 1.5 μg of Egr-1 reporter gene DNA (kindly provided by Dr William Aird, Beth Israel Deaconess Medical Center, Boston, Massachusetts, USA). Thirty hours post transfection, media was removed and cells were incubated with serum free medium for 16 hours to reduce background prior to stimulation with H. pylori or PMA (positive control) for four hours. Cells were then lysed and reporter activity measured in each sample using a luciferase reporter assay system (Promega) according to the manufacturer’s instructions. In some experiments, a plasmid construct encoding a dominant negative MEK1 (kindly provided by Dr Sang Hoon Rhee, Beth Israel Deaconess Medical Center) or vector alone was cotransfected with the Egr-1 construct. All assays were performed in triplicate and a single representative experiment is shown. Data are expressed as mean (SEM).

Statistical analyses

Statistical analyses were performed using Sigma-Stat for Windows version 2.0 (Jandel Scientific Software, San Rafael, California, USA). Analysis of variance followed by protected
RESULTS

Egr-1 is upregulated in *H pylori* infected gastric epithelial cells

Egr-1 is an immediate early gene and transcription factor that can be rapidly upregulated by numerous stimuli. Increased levels of Egr-1 can lead to changes in a number of biological processes, such as proliferation, inflammation, and cancer progression. To determine whether *H pylori* (cag+ ATCC strain 43504) could upregulate Egr-1, we infected AGS cells over a four hour time course with the bacteria and then examined whole cell lysates with an Egr-1 antibody. As shown in fig 1A, *H pylori* upregulated Egr-1 after one hour, this was maximal at two hours, and levels returned to baseline by four hours. Identical results to those seen with AGS cells were also seen with another gastric epithelial cell line, MKN-28 (data not shown).

To demonstrate that the Egr-1 upregulated in *H pylori* infected gastric epithelial cells is capable of binding to Egr-1 target genes, we isolated nuclear extracts from infected cells with *H pylori* over the four hour time course and performed an EMSA using an Egr consensus sequence. As shown in fig 1B, nuclear extracts from untreated cells showed little Egr-1 binding. After infection with *H pylori* for two hours, maximal binding occurred which was again reduced by four hours. To determine whether Egr-1 was binding to the probe, a supershift experiment was also performed. Nuclear extracts prepared from AGS cells were incubated with either an antibody to Egr-1 or Sp-1 as a control. The complex only underwent a supershift in the presence of the Egr-1 antibody (fig 1B, 5th lane, supershift indicated by arrow); in contrast no supershift was observed with the Sp-1 antibody. These results confirm that Egr-1 was present in the complex binding to our Egr consensus sequence.

*H pylori* infection results in increased Egr-1 mRNA expression and increases the activity of an Egr-1 luciferase reporter construct

We next examined whether infection of AGS cell with cag+ *H pylori* could increase Egr-1 mRNA expression. Analysis of cDNA by real time PCR revealed a 22-fold increase in Egr-1 mRNA levels at the two hour time point, which returned to baseline levels by six hours (fig 2A). These findings were confirmed by luciferase activity analysis, as described in the materials and methods section. The upper panel shows Egr-1 luciferase activity, values are expressed as mean (SEM); n = 3). ***p<0.001 versus unstimulated control.

*H pylori* infection results in increased Egr-1 mRNA expression. (A) Infection of AGS cells with *H pylori* resulted in an increase in Egr-1 mRNA expression over a six hour time course, as determined by real time polymerase chain reaction. Data were normalised to glyceraldehyde-3-phosphate dehydrogenase levels and results are expressed as fold induction above the unstimulated control. (B) *H pylori* infection upregulated Egr-1 luciferase reporter activity. Cells were transfected for 48 hours with an Egr-1 luciferase reporter construct. Cells were then treated with media alone (control), *H pylori* cag+ ATCC strain 43504 (MOI 20:1), or phorbol-12-myristate-13-acetate (PMA 10 nM) for four hours. Luciferase activity was then measured in cell lysates. Values are expressed as mean (SEM); n = 3). ***p<0.001 versus unstimulated control.

Figure 1  Early growth response gene 1 (Egr-1) is upregulated in *Helicobacter pylori* infected gastric epithelial cells. (A) Quiescent AGS cells were treated with *H pylori* cag+ ATCC strain 43504 (MOI 20:1) for the indicated times. Equal amounts of cell extracts were used to determine levels of Egr-1, as described in the materials and methods section. The upper panel shows Egr-1 levels present in cell lysates, the lower panel actin, which acts as a control for loading. The results are representative of three independent experiments. (B) Serum starved AGS cells were incubated with either an excess probe or antibodies (ab) against Egr-1 and Sp-1 and then subjected to a supershift experiment. Nuclear extracts from AGS cells were also seen with another gastric epithelial cell line, MKN-28 (data not shown).

Figure 2  *Helicobacter pylori* infection results in increased early growth response gene 1 (Egr-1) mRNA expression. (A) Infection of AGS cells with *H pylori* resulted in an increase in Egr-1 mRNA expression over a six hour time course, as determined by real time polymerase chain reaction. Data were normalised to glyceraldehyde-3-phosphate dehydrogenase levels and results are expressed as fold induction above the unstimulated control. (B) *H pylori* infection upregulated Egr-1 luciferase reporter activity. Cells were transfected for 48 hours with an Egr-1 luciferase reporter construct. Cells were then treated with media alone (control), *H pylori* cag+ ATCC strain 43504 (MOI 20:1), or phorbol-12-myristate-13-acetate (PMA 10 nM) for four hours. Luciferase activity was then measured in cell lysates. Values are expressed as mean (SEM); n = 3). ***p<0.001 versus unstimulated control.

Figure 3  Early growth response gene 1 (Egr-1) upregulation is mediated through contact between the bacterium and the cell. Serum starved AGS cells were exposed directly to *Helicobacter pylori* or cocultured with *H pylori* separated by a 0.1 µm filter that prevented direct contact between the bacteria and epithelial cells. The experiment was performed over a six hour time course and Egr-1 levels were analysed, as described in the materials and methods section. The upper panel shows Egr-1, the lower panel actin, used as a loading control. The results are representative of three independent experiments.
demonstrate that infection of AGS cells with *H pylori* results in a rapid but transient increase in Egr-1 mRNA levels, consistent with the Egr-1 protein data presented in fig 1. We examined whether infecting AGS cells with *H pylori* could induce activation of an Egr-1 luciferase reporter construct. AGS cells transfected with an Egr-1 reporter construct were treated with either *H pylori* or our positive control (PMA) for four hours and luciferase activity of the cells was then measured. Infecting AGS cells with *H pylori* resulted in a 2.9-fold increase in reporter activity while treatment with PMA resulted in a 4.7-fold increase above control (fig 2B).

**Egr-1 upregulation is mediated through contact between the bacterium and the cell**

Next we tested whether soluble factors produced by the bacterium played a role in Egr-1 upregulation or whether contact between bacterium and cell was necessary for induction using a Transwell system. We found that by preventing direct contact between AGS cells and the bacteria, upregulation of Egr-1 was completely prevented, suggesting that contact, and not soluble factors, plays a role in this process (fig 3).

**Egr-1 is differentially upregulated by cag+ and cag− strains of *H pylori***

Our group and others have previously shown that cag+ and cag− strains of *H pylori* are capable of differentially activating signal transduction pathways in gastric epithelial cells.** To determine whether Egr-1 was also preferentially upregulated by cag+ versus cag− strains of *H pylori*, we infected AGS gastric epithelial cells with a panel of three cag+ and 3 cag− strains of *H pylori* for two hours. Whole cell lysates were then analysed by western blotting using an Egr-1 specific antibody. As shown in fig 4A, cag+ strains of *H pylori* were capable of inducing Egr-1 production at two hours but in AGS cells infected with cag− strains, this induction did not occur. In addition, we also examined upregulation of Egr-1 in AGS cells infected with each of the six strains over a six hour time course. Figure 4B shows a complete six hour time course for the J166 cag+ strain and the J68 cag− strain, again demonstrating an increase in Egr-1 levels (3.2-fold) at two hours occurring with infection with the cag+ strain, but not with the cag− strain. As Egr-1 upregulation is known to be regulated via activation of the ERK1/2 signalling pathway,** we also analysed the blots for increases in ERK1/2 phosphorylation. Our findings (fig 4B) showed that increased ERK1/2 phosphorylation (2.4-fold at two hours) appeared to correlate with the increases seen in Egr-1 levels.

**Egr-1 upregulation by *H pylori* is dependent on an intact cag secretion system, but not CagA**

Previously, we and other investigators have shown that the cag pathogenicity island of *H pylori* plays an important role in activating various signal transduction pathways within gastric epithelial cells. To determine the importance of the cag secretion system to upregulation of Egr-1 by *H pylori*, we compared an isogenic cagE− mutant of *H pylori* with its parental strain. The cagE gene has previously been found to be essential to the functioning of the type IV secretion system. For this experiment we infected AGS cells with wild-type *H pylori* strain J166 or its cagE− isogenic mutant over a six hour time course. Lysates were then collected and analysed by western blotting to determine the level of Egr-1 present in the cells. As shown in fig 5A, the cagE− mutant had an impaired ability to upregulate Egr-1 protein levels compared with the parent strain. Analysis of Egr-1 mRNA levels by real time PCR also revealed that the cagE− mutant was much less efficient in upregulating Egr-1 mRNA levels (~10 fold less after two hours of infection) than its wild-type counterpart. ERK1/2 phosphorylation was also upregulated by the wild-type strain, but not the cagE− mutant at the two hour time point, again correlating with the increase in Egr-1 levels. These findings were confirmed using cagE− isogenic mutant derived from parental strain 60190 (data not shown).

We next examined whether CagA participated in *H pylori* mediated Egr-1 upregulation. Cells were incubated with wild-type *H pylori* strain 60190 or a cagA− isogenic mutant.
over a six hour time course and their ability to upregulate Egr-1 protein was examined. As shown in fig 5B, the cagA− mutant, unlike the cagE− mutant, had a similar ability to upregulate Egr-1 levels compared with the parental strain. These findings indicate that induction of Egr-1 in AGS cells, although requiring the participation of the type IV secretion system, is not dependent on translocation of CagA. Again, ERK1/2 phosphorylation was examined, and appeared to correlate with increases in Egr-1 levels. These results were also confirmed using our second set of isogenic mutants derived from cag+ strain 60190 (data not shown).

**ERK1/2 activation is required for Egr-1 upregulation in H pylori infected gastric epithelial cells**

We and other investigators have previously reported that H pylori can activate numerous signal transduction pathways, including the ERK1/2, p38, and c-Jun N-terminal kinase (JNK) MAP kinase pathways.16–24 Therefore, we investigated whether MAP kinase signalling pathways were involved in Egr-1 upregulation. AGS cells were treated with a number of pharmacological inhibitors, including the ERK1/2 inhibitor PD98059 (25 μM), p38 inhibitor SB203580 (10 μM), and the JNK inhibitor SP600125 (50 μM). Only the ERK1/2 inhibitor significantly decreased (69%) Egr-1 protein levels (fig 6A). Inhibitors of p38 and JNK were unable to prevent Egr-1 upregulation in H pylori infected cells (data not shown). These findings indicate that ERK1/2 phosphorylation in part is required for H pylori mediated Egr-1 upregulation in AGS cells. In order to confirm our pharmacological data that ERK1/2 was involved in this process, we utilised a dominant negative MEK1 construct, which was cotransfected into our cells along with our Egr-1 luciferase reporter construct. As shown in fig 6B, overexpression of dominant negative MEK1 resulted in a 40% and 75% reduction in basal and H pylori stimulated Egr-1 luciferase reporter activity, respectively, compared with cells cotransfected with the Egr-1 reporter and vector control.

**Egr-1 upregulation in H pylori can be downregulated by blocking epidermal growth factor receptor (EGFR) transactivation**

We have previously identified EGFR transactivation as one mechanism leading to the regulation of ERK1/2 phosphorylation by H pylori.20 We therefore examined whether blockade of EGFR kinase activity could similarly reduce H pylori stimulated Egr-1 protein levels. Cells were pretreated with the EGFR kinase inhibitor PD153035 (5 μM) for 30 minutes and then infected with H pylori over a four hour time course. Egr-1 protein levels were then examined by western blotting. As shown in fig 7, EGFR kinase inhibitor treatment resulted in partial blockade (~50%) of H pylori mediated Egr-1 upregulation. Similar data were also obtained with the EGFR kinase inhibitor AG1478 (1 μM). These findings indicate that EGFR transactivation plays a role in H pylori mediated Egr-1 upregulation in AGS gastric epithelial cells.

**DISCUSSION**

Previous studies have shown that infection with H pylori is associated with increased gastric epithelial cell proliferation.14 Increased cell turnover is an important risk factor for increased mutations and the progression to cancer. Egr-1 is a transcription factor that is able to regulate numerous genes involved in the proliferative response, which include metalloproteinases, growth factors, and their receptors.15 Therefore, Egr-1 upregulation may be an important event in H pylori associated cancer progression.

In this study, we showed that infection of gastric epithelial cells with H pylori resulted in a rapid but transient increase in Egr-1, both at the mRNA and protein levels. Although upregulation of Egr-1 in gastric epithelial cells by H pylori has previously been described by one other group,22 our study extends these observations in several important ways. We showed differences in induction of Egr-1 between cag+ and cag− H pylori, demonstrated the requirement for an intact type IV secretion system, and that H pylori mediated EGFR transactivation and ERK1/2 activation are upstream of Egr-1 upregulation.

One of the more significant findings of this study is that cagE− strains of H pylori are more potent in their ability to upregulate Egr-1 than cag+ strains. Furthermore, H pylori that have a non-functioning type IV secretion system due to mutation of the cagE gene also produce weaker activation of Egr-1.
Egr-1. In previous studies it has been shown that infection of gastric epithelial cells with either _H pylori_ cag+ and cag− strains results in divergent responses. Signal transduction pathways such as the MAP kinase cascades, activation of transcription factors such as nuclear factor-κB, and upregulation of other early response genes such as c-fos are all preferentially induced by cag+ strains. Infection with cag+ strains similarly results in upregulation of genes involved in the immune response, cell turnover, and apoptosis. This may explain why individuals infected with cag+ strains are more likely to develop atrophic gastritis and distal gastric cancer than those infected with cag− strains. We and others have shown that _H pylori_ are capable of causing transactivation of the EGFR via metalloproteinase dependent cleavage of HB-EGF. We have previously found that cag− strains of _H pylori_ are less able to induce transactivation of the EGFR than their cag+ counterparts. Likewise, mutants with disrupted type IV secretion systems are less able than their parental strains to induce EGFR transactivation. This in turn affects the ability of bacteria to induce early ERK1/2 phosphorylation, an event we have determined is necessary for Egr-1 upregulation. It has been found that ERK1/2 phosphorylation can also be mediated by soluble secreted factors that are independent of the cag PAL. Our Transwell experiments suggest that these soluble factors do not participate in the rapid Egr-1 upregulation observed in our model system. Infection of our cells with cagA− mutants resulted in a similar pattern of Egr-1 induction to that of the wild-type strain at early time points. However, later time points (>6 hours) were not examined in this study. Several groups have reported that _CagA_ interacts with numerous host proteins, including Grb2, which results in sustained activation of the MAP kinase pathway up to 24 hours. This may potentially lead to Egr-1 upregulation and thus we cannot rule out the possibility that CagA may have effects on Egr-1 upregulation at later stages.

In our in vitro model _H pylori_ induced Egr-1 upregulation appeared to be short lived. This is a typical activation pattern seen with other stimuli, including growth factors, hormones, and neurotransmitters. Egr-1 gene regulation is tightly controlled by two transcriptional cofactors termed NFGFI-A and NFB, and thus its continual activation over time may contribute to gastric epithelial cell hyperproliferation, a known risk factor for gastric carcinogenesis.

In addition to being upregulated in gastric cancer, Egr-1 has been found to play a particularly important role in prostate and breast cancer. Egr-1 expression levels are elevated in human prostate carcinomas in proportion to grade and stage, and in two models of prostate cancer, prostate cancer progression was found to be significantly delayed in mice lacking Egr-1. In a recent publication by Mitchell et al., DNAzymes targeting Egr-1 inhibited human breast cancer cell proliferation, migration, chemoinvasion, and solid tumour growth. Collectively, these findings together with the data presented in this study suggest that Egr-1 may play an important role in _H pylori_ mediated carcinogenesis.

Clinical presentation
A 64 year old man presented with a two month history of increasing dysphagia and weight loss. Upper gastrointestinal endoscopy was performed and a lesion was identified in the region of the gastro-oesophageal junction, which was biopsied. The patient then underwent both a $^{18}$F-fluorodeoxyglucose positron emission tomography study (fig 1) and a 16 detector computed tomography examination (fig 2).
