Introduction Hepatitis C virus (HCV) co-opts the VLDDL assembly, maturation, degradation, and secretory machinery of hepatocytes. Infectious low density particles have been termed lipoviral particles (LVP). LVPs in vivo are triglyceride (TG) rich and contain at least viral RNA, HCV core protein and the VLDDL components apolipoprotein B (apoB) and apoE. ApoE is a constituent of infectious HCV particles produced in cell culture, and production of infectious particles is dramatically impaired from cells in which apoE expression has been genetically silenced.

Aim To examine the relationship between LVP and apoE in vivo.

Method Fasting plasma samples were obtained from 59 chronic HCV genotype (G) three patients and 51 HCV G1 patients. LVP were measured using iodixanol density gradient ultracentrifugation as recently described. ApoE levels were determined by an automated immunonephelometric method. Demographic data were recorded and liver biochemical tests, lipid profiles and HOMA-IR were measured in all patients.

Results The mean LVP in HCV G3 was 5.2 log10 IU/ml with a mean LVP ratio of 0.286, but showed wide variation (0.03–0.96). This was not significantly different to LVP variation in HCV G1 we have previously reported. In HCV G1 we found a strong positive correlation of LVP HCV RNA with apoE levels (r=0.488, p=0.001) and also with LVP ratio (r=0.428, p=0.001). In contrast in HCV G3 we found a significant negative correlation of LVP HCV RNA with apoE levels (r=−0.428, p=0.013), suggesting different utilisation of lipoprotein pathways. We also found a negative correlation of LVP in HCV G3 with HDL cholesterol (r=−0.468, p=0.003) and its structural lipoprotein apoA1 (r=−0.479, p=0.002) whereas we have reported no correlation of LVP in chHGV1 with HDL or apoA1.

Furthermore in HCV G3 we found low TG levels compared to G1, and their components, rather than the parameters associated with TRL levels as in HCV G1. These differences highlight that inter-genotype differences in LVP may not only be dependent on the G1 infection but also on the paucity of HDL quantity and its components, rather than the parameters associated with TRL levels as in HCV G1. These differences highlight that inter-genotype differences in LVP may not only be dependent on infection but also on the paucity of HDL quantity and its components, rather than the parameters associated with TRL levels as in HCV G1.

Conclusion This study suggests that while serum apoE quantity is a positive determinant for LVP quantity in HCV G1 infection, it is a negative determinant in HCV G3 infection. Furthermore, LVP quantities in HCV G3 is largely based on the paucity of HDL quantity and their components, rather than the parameters associated with TRL levels as in HCV G1. These differences highlight that interaction with host lipoprotein metabolism is important for HCV infection in different genotypes, but in genotype specific ways.

P51  INTERFERON-INDUCED FATIGUE IN HEPATITIS C INFECTED PATIENTS IS ASSOCIATED WITH INCREASED EXPRESSION OF INDOLEAMINE 2,3-DIOXYGENASE IN PERIPHERAL BLOOD MONONUCLEAR CELLS

doi:10.1136/gutjnl-2011-300857a.51

Introduction Interferon-α (IFN)-based antiviral therapy for chronic hepatitis C virus (HCV) infection commonly induces fatigue and depression. IFN-induced symptoms may result from the activation of indoleamine 2,3-dioxygenase (IDO), the rate-limiting enzyme, regulating the breakdown of tryptophan (Trp) into L-kynurenine (Kyn), expressed in immune cells and brain. IDO activation might result in Trp and serotonin depletion and accumulation of neurototoxic Kyn metabolites. IFN increases IDO gene expression in vitro and increased serum Kyn/Trp ratios have been reported in IFN-treated patients. However, a consistent relationship between Kyn/Trp and IFN-induced symptoms in HCV has not been shown.

Aim We sought to determine the relationship between IDO mRNA expression in PBMC, serum Kyn/Trp ratio and IFN-induced symptoms.

Method Fatigue Impact Scale (FIS) and Hospital Anxiety and Depression (HADS-D) questionnaires were completed by 19 patients at baseline and after 12 weeks treatment with PegIFN-2a and ribavirin. Blood samples were taken from patients and 14 healthy controls. Total RNA was extracted from Ficol separated PBMC and IDO mRNA was quantified relative to GAPDH using RT-PCR (Applied Biosystems). Expression at week 12 vs baseline was calculated as fold change using the ΔΔCt-method. Serum Kyn/Trp was measured using HPLC/MS/MS.

Results IDO mRNA expression at baseline was similar in HCV patients and controls (ΔCt=−9.76±0.39, p=NS). In the whole cohort, there was no change in IDO expression at week 12 vs baseline (ΔCt=10.2±0.23 vs ΔCt=9.76±0.39, p=NS), although serum Kyn/Trp increased significantly (p<0.001). However, patients with IFN-induced fatigue (ΔFIS>20; n=7) showed increased IDO mRNA expression (ΔΔCt=−0.97±0.58; median fold change =2.57) vs those without fatigue (ΔΔCt=9.6±0.53; mfc=0.89, p=0.02). Only modest increases in depression scores were seen (ΔHADS-D ≥5 in 5 patients) but no differences in ΔΔCt were seen compared to those with unchanged HADS-D. Baseline IDO mRNA expression was not predictive of IFN-induced fatigue or depression. There were no associations between baseline or week 12 Kyn/Trp ratios and IFN-induced fatigue or depression.

Conclusion We show for the first time that peripheral IDO gene expression in HCV patients is similar to healthy controls and IFN-treatment leads to differential induction of IDO mRNA. IFN-induced fatigue is significantly associated with increased peripheral IDO expression but not serum Kyn/Trp. Measurement of PBMC IDO mRNA may mirror CNS changes more accurately than peripheral Trp and Kyn levels. The modest prevalence of depression in this small cohort may explain the lack of association with depression.

Introduction Hepatitis C virus (HCV) is a major risk factor for development of hepatocellular carcinoma (HCC), however, the mechanism of hepatocarcinogenesis in HCV infection is still undefined. Chemokines, which can induce the migration of leucocytes and activate inflammatory/immune responses, have recently been implicated in the regulation of tumour growth.

Aim Therefore, the aim of the present work was to study the role of macrophage inflammatory protein-1 α/CC chemokine ligand 3 (MIP-1α/CCL3), a potent macrophage chemoattractant, in the...
