the UK. Most series have however included smaller polyps (1 cm or less) and there is paucity of data on EMRs limited to large polyps. We report the outcomes on a series with large polyps (>2 cm) from a bowel cancer screening centre in the UK.

**Methods** A total of 5190 polypectomies were performed within the region from January 2008 to December 2011 on the Bowel Screening Programme. Data were collected from three hospitals on all large polyp EMR greater than 2 cm in size. Data were analysed using the SPSS V20.

**Results** A total of 61 patients with polyps 2 cm or greater were identified. The mean age was 69 years, 75% (n=46) of which were male. The mean size of the polyps resected was 35 mm (range 20–60 mm). The majority of the polyps were sessile (n=40) and located in the left colon (n=45). Tattooing was performed in 46% (n=28) and Argon-beam photocagulation (ABC) therapy was applied in 41% of cases (n=25). In 97%, the resections were complete (n=59). Histopathology results were obtainable in 57 patients of whom 12% (n=7/57) showed high grade dysplasia and 9% (n=5/57) were confirmed as adenocarcinoma. The overall major complication rate was 3% (n=2). Both complications were bleeding post-EMR. Surveillance data were available for 43 patients up-to 12 months post EMR. Six recurrences (10%) were seen at the EMR site at 3 months, five of these in left colon. On reviewing their initial EMR, the polyps had a median size of 25±6 mm; 50% (n=3/6) had APC therapy and 5/6 the excision was endoscopically complete on initial EMR. Histology confirmed low grade dysplasia (LGD) in all cases. Recurrence was endoscopically treated successfully in all cases. Recurrence rate was not influenced by the size or site of the polyp or APC therapy. Sessile polyp EMR were more likely to show recurrence (n=5/6). At 12 months, eight patients had recurrence. Six of these patients had endoscopically complete excision on initial EMR. On reviewing their initial EMR, the polyps had a median size of 35±5 mm; 50% had APC therapy. Recurrence was treated successfully in all cases.

**Conclusion** Endoscopic mucosal resection for large colorectal polyps is safe with relatively low complication rates compared to laparoscopic surgery. Recurrence rate is low at 3 months but can still occur up to 12 months in lesions felt to be completely excised.

**Competing interests** None declared.

**PWE-192** Efficacy and safety of extensive endomucosal resection for complete Barrett’s eradication in early Barrett’s neoplasia: A meta-analysis

**Introduction** The efficacy of complete Barrett’s eradication by extensive endomucosal resection (E-EMR) of Barrett's oesophagus with early cancer ranges from 60% to 100% with a post-resection stricture rate of up to 88% in a recent RCT. The primary aim of this meta-analysis was to determine the long-term efficacy and safety of E-EMR for complete Barrett’s eradication in patients with early Barrett’s cancer.

**Methods** MEDLINE, EMBASE and PubMed databases were searched using keywords, “Barrett’s oesophagus,” “oesophageal cancer,” “endomucosal resection,” “circumferential endomucosal resection,” Barrett’s high-grade dysplasia and Barrett’s intra-mucosal carcinoma from January 1965 to December 2011. Articles were selected/ reviewed and data collected based on pre-defined inclusion criteria, independently by two authors (RK and TT). Meta-analysis using random effects model was done.

**Results** Thirteen studies (N=691) were included in the final analysis. (586 males, average age, 65.9 range 45–67). 116 patients in six studies had long-segment Barrett’s. The average Barrett’s length was 3.78 cm (range 2–4.9 cm). Visible lesions were seen in 571/586 (65.3%) patients. At an average of 2 (range 1.5–2.5) EMR sessions, four resections (range 3–8) were done per session Complete Barrett’s eradication was achieved in 71.9% (95% CI 68.1% to 75.4%) and eradication of early Barrett’s cancer in 96% (95% CI 91% to 99%) of patients. At an average follow-up of 20.5 months (range 9–31.6) Barrett’s/dysplasia recurrence was seen in 13% (95% CI 10.7%–15.9%). Total number of resections (p=0.026) and age (p=0.057) were significant confounders for complete Barrett’s eradication. The overall stricture rate was 59% (95% CI 58%–64%). Procedure related perforations occurred in 12/691 (1.8%) and bleeding in 9.9% (95% CI 5.1%–13.5%) of patients. On meta-regression analysis there were no significant confounders for stricture formation.

**Conclusion** Complete long-term complete Barrett’s eradication in patients harbouring early cancer is effective in only 71.9% of patients with age and total endoscopic resections being significant confounders. The procedure appears safe but has a stricture rate of 59%.
