NO WAY BACK—IRREVERSIBLE ALTERATION OF THE GASTRIC AND OESOPHAGEAL MICRO-ENVIRONMENT FOLLOWING CHOLECYSTECTOMY
doi:10.1136/gutjnl-2012-302514a.155

S N S Gillani,* G Bass, T N Walsh. RCSI Academic Department of Surgery, Connolly Hospital, Dublin, Ireland

Introduction Background: Loss of the gallbladder reservoir function at cholecystectomy may critically alter the dynamics of bile storage and release. Consequent iatrogenic duodeno-gastro-esophageal reflux (DGER) may be associated with oesophago-gastric adenocarcinoma.

Aims To examine the histological and molecular effects of cholecystectomy on gastric and oesophageal mucosa.

Methods Patients and Methods: In a retrospective study we compared 26 gallstone-free controls with 25 patients pre-cholecystectomy and 29 patients post-cholecystectomy for one or more years. In a prospective study we compared 26 controls with 25 patients before and within 1 year of cholecystectomy. All underwent oesophago-gastro-duodenoscopy (EGD) with biopsies from the antrum, esophagogastric junction (EGJ) and 5 cm above the EGJ. A histochemical bile reflux index (BRI) was calculated and immunohistochemistry was performed for p53 and Ki67.

Results Results: In the retrospective study antral BRI positivity was 11% in controls vs 69% in cholecystectomy patients (p=0.001); at the EGJ BRI positivity was 19% in controls vs 41% in cholecystectomy patients (p=0.052). p53 was expressed at the antrum in 4% of controls vs 52% cholecystectomy patients (p=0.001) and in 19% vs 66% at the EGJ (p=0.001). Ki67 was expressed at the antrum in 23% vs 59% (p=0.001) and at the EGJ in 19% vs 62% (p=0.001). Prospectively, BRI positivity increased from 11% to 36% (p=0.001) at the antrum within 1 year of cholecystectomy. Ki67 expression increased from 19% to 48% (p=0.004) at EGJ in patients within 1 year of cholecystectomy while p53 remained unchanged.

Conclusion Changes attributable to DGER occur early in the gastric and LES mucosa of patients following cholecystectomy. Ki67 and p53 over-expression suggests that these changes may be precursors of malignant transformation. Such concerning changes suggest that options other than cholecystectomy be considered for patients with gallstones in a functioning gallbladder.

ANALYSIS OF COLORECTAL POLyps DETECTED IN THE ENGLISH NHS BOWEL CANCER SCREENING PROGRAMME WITH EMPHASIS ON ADVANCED ADENOMA AND POLYP CANCER DETECTED
doi:10.1136/gutjnl-2012-302514a.156

D Majumdar,* 2J Patnick, 2C Nickerson, 1M D Rutter. 1Department of Gastroenterology, University Hospital of North Tees, Stockton on Tees, UK; 2NHS Cancer Screening Programmes, NHS Cancer Screening Programmes, Sheffield, UK

Introduction Colorectal cancer is the second most common cause of cancer related death in the UK causing around 16 000 deaths each year. Colorectal adenomas are slow growing precursor lesions which progress to cancer. The lesion of most interest in this context is advanced adenoma (size 10+ mm/with 20%–25% villous histology/high grade dysplasia) as they are of higher risk of progression (2). This study analysed adenomatus lesions detected in NHS BCSP programme.

**Methods** Data on each patient entering the NHS BCSP programme is prospectively recorded on the national BCSP database. The database was interrogated for all polyps/adenomas found during the period September 2006 to September 2011. The data were analysed with particular focus on detection of advanced adenoma and polyp cancers.

Results A total of 65535 polyps were found, of which 43954 (67.06%) were confirmed histologically as adenomas. 15261 advanced adenomas were detected. These accounts for 34.7% of lesions removed and 25.9% of all lesions detected during screening. 842 polyp cancers were found and removed. 1.9% of the adenomatus lesions removed were polyp cancer. The incidence of villous morphology, HGD and polyp cancer, categorised by adenoma size, are shown in the Abstract OC-156 table 1. The presence of villous histology and high grade dysplasia increases with increasing size of adenoma, whereas villous histology begins to plateau for adenomas over 15 mm in size, the incidence of HGD appears linear up to and beyond adenomas of 45 mm in size.

Conclusion 67.06% of all lesions found were histologically confirmed colorectal adenomas. One third of adenomas were advanced adenomas. There is a trend of increase of incidence of cancer and features of advanced neoplasia in adenomas with increasing size. The incidence of AA feature present in lesions below 10 mm in size was 10.07%.
