signalling, in regulating intestinal epithelial apoptosis in vivo have not previously been investigated.

**Aims** To assess susceptibility to intestinal apoptosis and the associated molecular changes in mice with germline deletions of three individual NFκB family members.

**Methods** Intestinal apoptosis was induced in male c-Rel-null, NFκB1-null and NFκB2-null mice and their wild-type (C57BL/6) counterparts by 8Gy γ-irradiation (n=6 per group). Apoptosis was assessed on a cell positional basis from H/E stained sections. The mRNA expression of 10 key apoptosis regulating genes in the small intestine and colon (TRAIL, Caspase12, BAK, FAS-L, FAS, p53, BCL2, BCL-XL, c-IAP2 and XIAP) was assessed by real time PCR (n=4 per group). Statistical comparisons were by ANOVA with Bonferroni post-hoc tests.

**Results** Basal small intestinal crypt apoptosis was significantly increased in NFκB2-null relative to C57BL/6 mice. In addition, small intestinal and colonic crypt apoptotic indices were both significantly increased (up to threefold) in NFκB1-null and NFκB2-null mice 4.5 h after 8Gy γ-irradiation relative to wild-type and c-Rel-null mice. Untreated NFκB1-null and NFκB2-null small intestine showed reduced mRNA expression of the anti-apoptotic genes BCL2, BCL-XL, c-IAP2 and XIAP. Following irradiation, NFκB1-null mice showed significant increases in the mRNA of the pro-apoptotic genes TRAIL, Caspase12 (in both small intestine and colon) and BAK (small intestine only) compared to wild-type mice. Significant increases in the mRNA of the pro-apoptotic genes Caspase12 and FAS-L were also seen in irradiated NFκB2-null small intestine and colon relative to wild-type mice.

**Conclusion** c-Rel expression does not appear to regulate susceptibility to intestinal epithelial apoptosis in vivo. NFκB1 and NFκB2 deletion both caused increased susceptibility to intestinal apoptosis and this was associated with altered expression of TRAIL, Caspase12, BAK and FAS-L. These NFκB family members may therefore also regulate the susceptibility of intestinal epithelia to other consequences of DNA damage such as cancer.

**OC-020 RECURRENT AFTER RADIOFREQUENCY ABLATION FOR BARRETT’S RELATED HIGH GRADE DYSPLASIA IS DUE TO PERSISTENCE OF EPITHELIAL MUTATIONS**

doi:10.1136/gutjnl-2012-302514a.20

1S Zeiki,* 2L Lovat, 3H Barr, 4H Shepherd, 5M Rodriguez-Justo, 6N Wright, 4S McDonald, 5M Novelli, 6Department of Digestive Diseases, Blizard Institute, London, UK; 2Department of Gastroenterology, UCLH, London, UK; 3Department of Surgery, Gloucester Royal Hospital, Gloucester, UK; 4Department of Histopathology, Gloucester Royal Hospital, Gloucester, UK; 5Department of Histopathology, UCLH, London, UK; 6Centre for Digestive Diseases, Blizard Institute, London, UK

**Introduction** Radiofrequency ablation (RFA) is a relatively new endoscopic method for ablation of high grade dysplasia (HGD) and intramucosal adenocarcinoma (IMC) in Barrett’s oesophagus. Clinical trials have shown enduring eradication of these pathologies. However, some patients develop recurrent dysplasia or cancer. The reason for this is unknown. The aim of the study was to investigate whether this is related to the persistence of known cancer driving mutations after radiofrequency ablation.

**Methods** Patient records were searched for patients with recurrent HGD or IMC after RFA. Biopsies and endoscopic mucosal resection (EMR) specimens were available before and after RFA for each case. Whole biopsies underwent nested polymerase chain reaction (PCR) sequencing for mutations commonly implicated in progression to adenocarcinoma (TP53, CDKN2a, K-ras).

**Results** Tissue was obtained for six patients before and after RFA. All patients were male (mean age 67 SD±2). Samples from five patients contained detectable mutations. In 3/5 patients, the same mutation was found in material taken before RFA as after (all TP53 mutations). The indication for RFA in all three patients was HGD; two of the patients developed IMC after RFA. In these two cases laser microdissection was performed on the post-RFA EMR samples. PCR revealed the pre RFA mutation to also be present throughout the IMC specimen. Dysplastic tissue adjacent to the IMC contained a mixture of crypts that were either wild type for the mutation in the IMC or contained the mutation indicating that the IMC was a monoclonal outgrowth and that the persistent mutation was driving the development of the recurrence. Furthermore, in all three cases, PCR of a further specimens (performed at a later time point to the first post-RFA EMR), revealed the same mutation as the initial biopsy before RFA, and the first post-RFA EMR.

**Conclusion** The recurrence of dysplasia and cancer after RFA is likely to be due to failure to remove persistent, cancer driving mutations. Further work will need to be done to assess whether this is because of technical errors, or related to specific problems such as “buried Barrett’s”.

**OC-021 A NOVEL SUBSET OF FUNCTIONAL IL-10 SECRETING CD8+ REGULATORY T CELLS INFILTRATE HUMAN HEPATOCELLULAR CARCINOMA**

doi:10.1136/gutjnl-2012-302514a.21

K K Li,* S Ward, S Curbishley, D Adams. Centre for Liver Research, NIHR Biomedical Research Unit, University of Birmingham, Birmingham, UK

**Introduction** Tumour specific effector T-cells can be detected in the blood and tumours of patients with hepatocellular carcinoma but fail to mount effective immune responses. Attempts to amplify anti-tumour immune responses using immunotherapy show promise, but are hampered by the presence of suppressive regulatory T-cells (Tregs) that inhibit anti-tumour immune responses. Tregs are crucial in the maintenance of immune homeostasis and in the prevention of auto-reactive immune response but in the context of cancer they can suppress beneficial anti-tumour immunity leading to tumour progression. A novel subset of CD8 expressing Tregs has recently been described and we now report the presence of such cells in human hepatocellular carcinoma and define their functional and homing properties.

**Methods** Fresh tissue from hepatocellular carcinoma and matched distal non-involved tissue was obtained from patients undergoing liver resection or transplantation at the Queen Elizabeth Hospital, Birmingham after informed consent. Liver-derived T-cells were isolated and phenotyped using multi-colour flow cytometry including intracellular cytokine staining. CD8+ Tregs were isolated using a Mo-Flow cell sorter for functional assays. Distribution of CD8+ Tregs was investigated by immunohistochemistry and immunofluorescence.

**Results** The percentage of CD8+ Tregs (defined as CD8+CD28highCD127lowFoxP3−) infiltrating hepatocellular carcinoma tumours was significantly greater compared with matched non-involved liver. Tumour-derived CD8+ Tregs isolated by MoFlo sorting suppressed alloreactive effector cells in vitro and secreted interleukin-10 (IL-10). In contrast T-cell interferon-γ (IFN-γ) production was decreased within the tumour compared with matched non-involved liver. The chemokine receptor CXCR3 which is involved in T-cell recruitment to the inflamed liver was highly expressed on tumour-derived CD8+ Tregs.

**Conclusion** A novel subset of functional IL-10 secreting CD8+ Tregs may suppress anti-tumour immunity in hepatocellular carcinoma.
Their expression of CXCR3 provides a potential mechanism for recruitment into the tumour environment.

OC-022 EMBOLISATION OF INFLOW TO ALLOW SAFER LIVER RESECTION — IS MORE, BETTER?

R Lochan,* A Vallance, J French, R Charnley, B Jaques, J Rose, S White, D Manas. HPB Liver Transplantation Surgery, FH, Newcastle Upon Tyne, UK

Introduction Portal vein embolisation (PVE) is now an established technique to increase the future liver volume/remnant (FLR) prior to liver resection. For those patients where hypertrophy is still considered insufficient complete uni-lateral embolisation incorporating both portal and hepatic artery embolisation (HAE) has been less frequently reported. The aim of this study was to evaluate the feasibility of sequential PV/HAE embolisation to increase the FLR prior to liver resection.

Methods All HPB patients are discussed at a weekly MDT meeting to decide on appropriate management decisions including the necessity for FLR augmentation. PVE is performed by initially obtaining a portogram by percutaneous trans-hepatic puncture. Selective embolisation of the necessary portal veins are then performed using a combination of coils and glue etc. Embolisation of Segment 4 PV branches are performed on a selective basis. HA embolisation is performed by mapping arterial inflow and selectively embolising the desired segments planned for resection while carefully preserving the FLR. The aim of this study was to evaluate the feasibility/safety of PVE with sequential HAE over a 5-year period (January 2006—May 2011).

Results 50 patients (M:F = 38:12) underwent a right PVE; 33 (66%) progressed to liver resection. Reasons for inoperability (34%) following PVE (n=17) were (1) Small FLR, (n=6) all underwent HAE (with five proceeding to resection) (2) extra-hepatic disease (n=7) (3) progression of hepatic disease (n=4). The median FLR of those who progressed to resection following PVE, by CT volumetry, was 384.5 cc (330 flR of those who progressed to resection following PVE, by CT

Conclusion PVE is an increasingly used technique to increase the FLR less frequently reported. The aim of this study was to evaluate the feasibility of sequential PV/HAE embolisation to increase the FLR prior to liver resection.

OC-024 DEVELOPMENT AND VALIDATION OF A NOVEL CAPTURE-FUSION MODEL FOR HCV REPLICATION

M E Cunningham,* A Javaid, J A Waters, G R Foster. Blizard Institute of Cell and Molecular Science, Queen Mary, University of London, London, UK; Vale of Leven District General Hospital, Glasgow, UK

Introduction HCV replicates poorly in vitro, so testing of novel antiviral therapies currently relies on modified viral replicons, based on genotype (G)1, or the G2 JFH-1 virus. A model allowing patient virions to be cultured would facilitate drug discovery and allow direct sensitivity testing. Here we describe the development of a novel HCV replication assay, its validation using the antiviral agents alisporivir and telaprevir and its value in identifying responses to interferon and ribavirin.

Methods CD14 (+) monocytes derived from patients with chronic HCV infection, or pre-stimulated THP-1 cells infected with serum albumin G1 and G3 HCV infected donors, were fused with HuH7 cells and treated with antiviral agents at various concentrations. The fused cells were maintained in tissue culture for up to 5 days, before adsorption to adsorb endotoxin and replace damaged albumin in patients' plasma.

Conclusion These results confirm that UCL-ARSeNEL improves survival in ALF by addressing key pathophysiological derangements such as albumin dysfunction and endotoxinaemia; which impact upon systemic inflammation and end-organ function. The reduction in inflammation is associated with improved vascular function and reduced inotropic support requirements.
