Introduction

Celiac disease (CD) is an autoimmune disorder that is triggered by an immune response to gluten in genetically predisposed individuals. Interleukin-8 (IL-8) is produced by macrophages, epithelial cells and endothelial cells. Therefore, IL8 has an important role in the innate immune response and associated with inflammation. The aim of this study is to evaluate the elevation of IL8 level in patients with celiac disease compared with control group.

Methods

Fifty three confirmed treated or untreated celiac disease patients referred to Taleghani hospital, Iran as cases were matched according to age and gender with 300 healthy controls, screened with ELISA to determine the level of IL8.

Results

Serum IL8 levels were evaluated in all patients with positive CD compare to healthy control. The minimum level of IL8 in cases was 16.3 and maximum level was 397.7. On the other side the minimum and maximum level of IL8 in controls was 10.3 and 397.7 respectively. The mean level of IL8 in celiac disease patients was 116.8 compare with 84.8 in healthy control. This differences was statistically significant between 2 groups ($p = 0.0001$).

Conclusion

Increased serum levels of pro-inflammatory cytokines such as IL8 seem to be increased in patients with celiac disease. It is the inflammation inherent in gluten sensitivity rather than mucosal atrophy that results in malabsorption and nutrient deficiency. Our findings suggest that higher level of IL8 in patients with celiac disease characterise the higher inflammatory response of this disease in the active phase. The inflammatory response including increasing the level of IL-8 may cause or not damage to the intestinal mucosa but in both cases lead to increased permeability of the intestinal epithelium.

Disclosure of Interest

None Declared.
differentiation between wind and solid had a positive correlation with better QOL (p = 0.007 and 0.02 respectively). There was a non-significant decrease in the overall QOL (EQ-5D p = 0.6, EQ-VAS p = 0.12) following hemicolectomy compared with controls.

Conclusion Colonic resection has an adverse effect on bowel frequency with worse outcomes following right hemicolectomy. Good colonic function, as assessed by the MSKCC questionnaire, is associated with better QOL.

PWE-002 SHORT-TERM OUTCOMES FOLLOWING SURGICAL TREATMENT OF BENIGN COLONIC POLyps: A CASE-MATCHED STUDY
doi:10.1136/gutjnl-2013-304907.291

1 M Verma, 2 P Wurm, 1 A Dixon, 3 K P West, 1 A P Chilton. 1 Gastroenterology, Kettering General Hospital NHS Foundation Trust, Kettering; 2 Gastroenterology; 3 Pathology, University Hospitals Leicester NHS Trust, Leicester, UK

Introduction Patients diagnosed with complex colonic polyps (broad based, crossing two haustral folds, or being located at the ileocecal valve or colonic flexures) unsuitable for endoscopic treatment undergo the same surgical procedure as patients with colon cancer. As a result of the bowel cancer screening programmes, the number of these patients has increased significantly and outcomes after hemicolectomy for benign colonic polyps (BCP) are poorly documented. We present a case-matched study examining short-term outcomes of patients with BCP versus those with colonic cancer (CC) from two institutions.

Methods Consecutive patients undergoing surgery for BCP were identified in two hospitals from prospectively maintained databases (data collection period 2005–2006 and 2010–2012 respectively). Hospital coding database was also searched using operation codes to identify missing patients. Each patient was matched for age, sex, ASA grade, site and type of resection (laparoscopic, open, and converted) to two controls undergoing surgery for treatment of CC identified in each centre. The length of stay (LOS) and 30-day outcomes were analysed with further adjustments for BMI, blood loss and operation time. Multilevel linear and logistic regression analyses were performed.

Results 46 BCP patients were matched with 81 CC patients. Almost all procedures were performed laparoscopically (42/46). Two procedures were converted to open and two patients underwent planned open surgery. Median size of BCP was 4 cm (IQR 2.5, 5.4). BCP group had a marginally longer LOS [median 5.5 days (IQR 4, 8)] and 5 days (IQR 3, 7) respectively (p = 0.04). 21/46 (46%) patients with BCP had a postoperative complication compared to 25/81 (31%) CC patients (p = 0.12, OR = 2.11; CI 0.82-5.41). 4/46 (9%) BCP patients underwent reoperation and further 3/46 (7%) were readmitted versus 1/81 (1%) and 2/81 (2%) in CC group (p = 0.07 and 0.28 respectively). No deaths were observed in either group.

Conclusion Complications following segmental colectomy for complex colonic polyps are not significantly different to those after cancer surgery. The results of this study provide further impetus for the development of a local full thickness colonic excision technique as an alternative, less invasive treatment option in order to improve patient outcomes.

PWE-003 COLORECTAL CANCERS ARISING IN ADENOMAS (“POLYP CANCERS”) DISCOVERED AND RESECTED DURING BOWEL CANCER SCREENING COLONOSCOPY
doi:10.1136/gutjnl-2013-304907.292

1 AM Verma, 2 P Wurm, 1 A Dixon, 3 K P West, 1 A P Chilton. 1 Gastroenterology, Kettering General Hospital NHS Foundation Trust, Kettering; 2 Gastroenterology; 3 Pathology, University Hospitals Leicester NHS Trust, Leicester, UK

Introduction The national bowel cancer screening programme (BCSP) was rolled out in 2006. Screening is based on a guaiac FOBT strategy, positive tests are offered colonoscopy. In January 2008 implementation commenced in LNR region (pop ~1.6 million).

Polymp cancers present a challenge both to clinicians and patients - optimal management remains unclear. We prospectively followed all patients who underwent primary endoscopic polypectomy.

Methods Patients with polyp cancers resected by polypectomy alone within the BCSP (48 cases as of 31/12/11) have had their outcomes recorded (last update 31/10/12).

Results Demographic data
Mean/median age = 65.92/66 yrs
Males/Females = 33 (68.75%)/15 (31.25%)
Location of polyp cancer
Rectum = 5 (10.4%)/Sigmoid = 41 (85.4%)/Desc colon = 2 (4.2%)

Notes One patient with a Haggitt 1 polyp cancer has subsequently died from ascending colon adenocarcinoma (a new lesion). Of the 13 other polyp cancers, 5 were pedunculated but not assigned Haggitt levels due to incomplete excision or invasive cancer – one of these patients has subsequently died with liver metastases. There were 8 sessile polyp cancers with no recurrences – too small a group to draw any meaningful conclusions.

Conclusion There were 26 patients with Haggitt 1 or 2 polyp cancers. Cumulative follow up of 73.3 yrs has not identified any case of recurrence, suggesting that endoscopic resection of these lesions is curative. The 9 patients with Haggitt 3 polyp cancers (invasion into stalk) have 30.3 yrs cumulative recurrence free time.

It is recognised that there is an increased risk of adverse outcomes (lymph node metastasis/recurrence) from Haggitt 4 polyp cancers (invasion into bowel wall submucosa below stalk) and hence factors such as adequate resection margins (despite diathermy artefact) and length of stalk have to be taken into account to ensure that Haggitt 3 polyp cancers are not actually Haggitt 4 polyp cancers.

Patients with Haggitt 3 polyp cancers, where there is evidence of adequate resection margins, should be offered the option of conservative treatment balanced with the risks of formal resection.

PWE-004 DETECTION OF VENOUS INVASION TO STAGE COLORECTAL CANCER
doi:10.1136/gutjnl-2013-304907.293

1 A M Verma, 2 P Wurm, 1 A Dixon, 3 K P West, 1 A P Chilton. 1 Gastroenterology, Kettering General Hospital NHS Foundation Trust, Kettering; 2 Gastroenterology; 3 Pathology, University Hospitals Leicester NHS Trust, Leicester, UK

Introduction Elastica staining of tumour sections increases the sensitivity of detection of venous invasion in colorectal cancer. We compared the prognostic value of elastica detected venous invasion with that of other pathological features in colorectal tumours.
