cases were 60% and 25%, respectively. At present, the median survival period after recurrence of operation cases was longer than that of contraindication cases (37 months vs. 13 months). Our results suggested that one FDG-PET oriented operation roughly corresponded to one year survival benefit with restart.

**Conclusion** Conclusion: FDG-PET could identify malignant lesions at earlier stage, and was an effective modality to evaluate not only disease spread but distant metastasis for recurrence of colorectal cancer. In this study, we first concretely demonstrated that FDG-PET oriented surgical indication had survival benefit for recurrent colorectal cancer.

**OC-087** SCREEN-DETECTED COLORECTAL CANCERS ARE ASSOCIATED WITH AN IMPROVED OUTCOME WHEN COMPARED WITH INTERVAL CANCERS WHEN MATCHED FOR STAGE

doi:10.1136/gutjnl-2013-304907.086

1,2,3M D Gill, 2,3M Bramble, 4M Hull, 1,2S Mills, 1E Morris, 1,2M Bradburn, 1Y Bury, 5,6C Parker, 6T Lee, 2,3,6C Rees. 1Northern Colorectal Cancer Audit Group, Northumberland; 2University of Durham, Durham; 3Northern Region Endoscopy Group, North East UK; 4University of Leeds, Leeds; 5Royal Victoria Infirmary, Newcastle; 6South Tyneside Foundation Trust, South Tyneside, UK

**Introduction** Colorectal cancers detected through the NHS Bowel Cancer Screening Programme (BCSP) have been shown to have a more favourable outcome compared to non-screen detected cancers. The aim of this study was to identify whether this was solely due to the earlier stage shift of these cancers, or whether there were other factors involved.

**Methods** A combination of a regional colorectal cancer registry (Northern Colorectal Cancer Audit Group) and the BCSP database were used to identify screen detected cancers and interval cancers (diagnosed after a negative faecal occult blood test, before the next screening round). All cancers were diagnosed between April 2007 and March 2010, within the North East of England. For each Dukes’ stage, patient demographics, tumour characteristics, and survival rates were compared between the screen detected and interval cancer groups.

**Results** 822 screen detected cancers were compared against 192 interval cancers.

Significant differences highlighted in bold, p < 0.05. Mean follow-up 32 months.

**Conclusion** With equivalent patient demographics and tumour characteristics, the improved survival of screen detected cancers over interval cancers for Stages C and D suggest that there may be a biological difference in the cancers in each group. Although lead-time bias may have a role, this may be related to a tumours propensity to bleed and therefore may reflect detection through current screening tests.

**OC-088** PROSPECTIVE PILOT STUDY TO INVESTIGATE TRANSCUTANEOUS SACRAL NERVE STIMULATION FOR Faecal Incontinence

doi:10.1136/gutjnl-2013-304907.087

1,2,3G Thomas, 1C Norton, 1R J Nicholls, 1C Vaizey. 1St Mark’s Hospital and Academic Institute, London, UK

**Introduction** Sacral nerve stimulation (SNS) is an effective treatment for faecal incontinence (FI). However it is expensive, it requires two operations and has a risk of infection, implant migration and pain. Transcutaneous SNS is non-invasive and cheap. Only one small study has previously reported its use for FI. The aim of this study is to further assess the efficacy of transcutaneous SNS for FI.

**Methods** Recruited patients self-administered transcutaneous SNS for 12 hours a day, over four weeks. A two week bowel diary was kept for the final two weeks and compared to baseline. St Marks FI scores, a visual analogue scale assessing satisfaction with bowel habit, Rockwood FI QOL scores and SF-36 QOL scores were obtained.

**Results** Ten patients were recruited. Two achieved complete continence. There were significant reductions in the frequency of FI episodes per week, 9.5 (7.5) to 3 (7.38); p = 0.03, and in the frequency of defecation per week, 25.5 (19.5) to 14.5 (14.9); p = 0.007. There was a significant improvement in the ability to defer defecation (1.25) to 4.5 (4.5) minutes, p = 0.02. There was a significant improvement in the St Marks FI score, 20 (5.25) to 14.5 (8.0); p = 0.01. There was a significant improvement in the bowel habit satisfaction visual analogue scale 8.5 (20) to 45 (33); p = 0.008. There were no significant changes in the Rockwood FI QOL score, or in the SF-36 QOL score. No complications were reported.

**Conclusion** Transcutaneous SNS appears to be an effective and safe treatment for FI.

**OC-089** EPIGENETIC CONTROL OF GI INFLAMMATION VIA THE METHYL-BINDING PROTEIN MBDB

doi:10.1136/gutjnl-2013-304907.088

1,2,3G R Jones, 1P Cook, 1L Webb, 1A MacDonald. 1University of Edinburgh, Edinburgh, UK

**Introduction** Methyl-CpG binding protein domain protein-2 (Mbd2) is a transcriptional co-repressor that binds to methylated DNA. Mbd2 can recruit a nucleosome remodelling complex which contains chromatin remodelling and histone deacetylase properties. Mbd2 deficient mice are viable and fertile. However, they display a dysregulated immune phenotype with an aberrant T cell cytokine response and susceptibility to intestinal helminth infection (1). This immunological phenotype has not been explored in the GI tract.
