ABSTRACT
Objective Butyrate exerts metabolic benefits in mice and humans, the underlying mechanisms being still unclear. We aimed to investigate the effect of butyrate on appetite and energy expenditure, and to what extent these two components contribute to the beneficial metabolic effects of butyrate.

Design Acute effects of butyrate on appetite and its method of action were investigated in mice following an intragastric gavage or intravenous injection of butyrate. To study the contribution of satiety to the metabolic benefits of butyrate, mice were fed a high-fat diet with butyrate, and an additional pair-fed group was included. Mechanistic involvement of the gut-brain neural circuit was investigated in vagotomised mice.

Results Acute oral, but not intravenous, butyrate administration decreased food intake, suppressed the activity of orexigenic neurons that express neuropeptide Y in the hypothalamus, and decreased neuronal activity within the nucleus tractus solitarius and dorsal vagal complex in the brainstem. Chronic butyrate supplementation prevented diet-induced obesity, hyperinsulinaemia, hypertriglyceridaemia and hepatic steatosis, largely attributed to a reduction in food intake. Butyrate also modestly promoted fat oxidation and activated brown adipose tissue (BAT), evident from increased utilisation of plasma triglyceride-derived fatty acids. This effect was not due to the reduced food intake, but explained by an increased sympathetic outflow to BAT. Subdiaphragmatic vagotomy abolished the effects of butyrate on food intake as well as the stimulation of metabolic activity in BAT.

Conclusion Butyrate acts on the gut-brain neural circuit to improve energy metabolism via reducing energy intake and enhancing fat oxidation by activating BAT.

INTRODUCTION
A positive energy balance, which occurs when energy intake exceeds energy expenditure, leads to the development of obesity. The prevalence of obesity has been increasing steadily over the past two decades, and obesity is becoming a global health concern. Obesity and obesity-initiated diseases are associated with high mortality and morbidity, mainly related to diabetes mellitus and cardiovascular disease. Obese individuals have enhanced appetite and/or reduced energy expenditure, mainly due to insufficient physical activity and impaired brown adipose tissue (BAT) activity. BAT contributes substantially to energy expenditure by combusting large amounts of triglycerides (TG) and glucose in humans (reviewed in refs 5 6), and its activity is mainly regulated through the sympathetic nervous system (SNS) under the control of the hypothalamic nuclei. The hypothalamus is also the central key regulator of food intake and...
energy intake, receiving hormonal and neural signals emanating from the GI tract, adipose tissue and other peripheral organs. Although several pharmaceutical agents have been approved for the treatment of obesity, the clinical application of these agents for long-term body weight management is hampered due to the high incidence of adverse events. The fundamental approach for combating against obesity is still lifestyle intervention, including diet adjustment.

Dietary fibre is deemed to be a key component in the healthy eating, mainly because dietary fibre is the main resource for production of endogenous short-chain fatty acids (SCFA) during bacterial fermentation in the colon. Interestingly, dietary supplementation of SCFAs has been shown to protect from obesity, making SCFAs promising candidates for the prevention of metabolic disorders. Of the SCFAs, in particular butyrate supplementation was found to have profound multiple metabolic benefits, including prevention of high-fat diet (HFD)-induced obesity, insulin resistance and hepatic steatosis. A reasonable speculation is that butyrate acts on components of the energy balance, that is, stimulating energy expenditure, and/or reducing energy intake, thereby reducing obesity and obesity-associated disorders. A previous study indeed showed that butyrate induced peroxisome proliferator-activated receptor-α/γ activity, thereby enhancing mitochondrial function in BAT and substantially promoting energy expenditure. On the other hand, the effect of butyrate consumption on appetite is rather obscure. Whereas at least one study showed a clear reduction in food intake upon butyrate intervention, other studies reported that dietary supplementation of butyrate did not alter food intake in diet-induced obese mice. Interestingly, clinical studies showed that dietary fibre, that is, oligofructose, increases endogenous butyrate production, accompanied by a reduction in energy intake.

By using APOE*3-Leiden.CETP mice, a well-established translational model for developing human-like diet-induced obesity, dyslipidaemia and metabolic syndrome, we now aimed to evaluate the effect of butyrate on energy intake and energy expenditure with respect to BAT activity, and to dissect the contribution of these two components of the energy balance to the metabolic benefits of butyrate. Here we provide first evidence that oral butyrate via the gut-brain neural circuit reduces appetite and activates BAT.

**MATERIALS AND METHODS**

Please see online supplementary materials and methods for an expanded version of this section.

**Animals**

APOE*3-Leiden.CETP (E3L.CETP) mice were obtained as previously described and housed under standard conditions in conventional cages with free access to chow diet and water unless indicated otherwise. At the age of 10–12 weeks, male mice were used for experiments in accordance with the regulations of Dutch law on animal welfare.

**Chronic intervention experiment**

Mice received an HFD (60% kcal derived from lard fat and 0.25% cholesterol (w/w), Research Diets, New Brunswick, NJ) without (control group) or with 5% (w/w) sodium butyrate (Sigma Aldrich; butyrate group) for 9 weeks. Since butyrate was expected to reduce food intake, a third group of mice received the same amount of HFD as that of the butyrate group (pair-fed group).

**Subdiaphragmatic vagotomy surgery**

Mice received subdiaphragmatic vagotomy surgery or sham surgery as controls. After a recovery period of 1 week after the surgery, mice received an HFD alone or supplemented with 5% (w/w) sodium butyrate for 7 weeks.

**Statistical analysis**

All data are expressed as mean±SEM. For studies including three groups, differences between groups were determined using one-way analysis of variance test. When significant differences were observed, Fisher’s least significant difference test was used as a post hoc test to determine the differences between two independent groups. For studies including two groups, statistical differences between groups were calculated using a two-tail unpaired Student’s t-test. A P value less than 0.05 was considered statistically significant.

**RESULTS**

**Oral rather than intravenous butyrate decreases food intake and inhibits orexigenic neuron activity in hypothalamus**

We first evaluated the effect of butyrate on appetite. In overnight fasted mice, butyrate administration via intragastric gavage significantly prevented food intake within 1 hour after refeeding, and led to a 21% reduction in cumulative food intake over 24 hours (figure 1A). This acute reduction in food intake was accompanied with a large decrease in number of FOS-positive neurons within the arcuate nucleus in the hypothalamus (−73%, figure 1B). Furthermore, oral butyrate markedly decreased the portion of neuropeptide Y (NPY)-positive neurons that also express c-FOS (−49%, figure 1C), while did not influence the portion of pro-opiomelanocortin-positive neurons coexpressing c-FOS (figure 1D). In addition, oral butyrate clearly decreased the number of FOS-positive neurons within nucleus tractus solitarius (NTS) and dorsal vagal complex (DVC) in brainstem (−37%, figure 1E), without affecting the neuronal activity in either cortical region or hippocampal region (data not shown). Notably, 1 hour after gavage, oral butyrate supplementation raised the portal vein and peripheral circulating butyrate concentration as compared with the control group. To elucidate whether the increased circulating butyrate evoked the reduced appetite, we also administered butyrate directly into the circulation by intravenous injection. As a result, the circulating butyrate concentration markedly increased (online supplementary figure S1), however without influencing either acute refeeding or food intake within 24 hours (figure 1F). Collectively, these data imply that oral administration of butyrate reduces food intake and hypothalamic neuronal signalling independent of increased circulating butyrate levels, indicating a mechanism involving the gut-brain neural circuit.

**Butyrate consumption prevents HFD-induced obesity and hepatic steatosis, mainly via reducing food intake**

To evaluate the contribution of reduced food intake to the metabolic benefits of chronic butyrate treatment, we fed E3L.CETP mice an HFD without or with sodium butyrate for 9 weeks, and included an additional group that was pair-fed to the butyrate group while receiving HFD. In line with the acute reduced appetite effect of a single oral butyrate administration, chronic dietary butyrate supplementation also caused a sustained reduction in food intake during the 9-week intervention period (figure 2A), resulting in 22% less food intake as compared with that of the control group (figure 2B).
We observed that butyrate completely prevented HFD-induced body weight gain (figure 2C), accompanied by decreased fat mass gain (figure 2D) without affecting lean mass as compared with the control group. Of note, during the first 7 weeks, food restriction per se by pair feeding diminished diet-induced obesity to a similar extent as observed by butyrate supplementation (figure 2C). After 9 weeks of intervention, as compared with control group, butyrate supplementation decreased body weight by −27% (figure 2E) and the weight of the gonadal (g) white adipose tissue (WAT) pad by −69% (figure 2F); while pair feeding decreased body weight by −18% (figure 2E) and the weight of the gWAT pad by −42% (figure 2F). This suggests that the antiobesity action of butyrate is largely dependent on reduction of food intake.

Butyrate also decreased liver weight (−25%, figure 2G), hepatic TG and phospholipid content (figure 2H) as compared with the HFD control group. Chronic butyrate consumption did not alter the levels of acetate, propionate and butyrate in peripheral blood, nor in portal vein blood (online supplementary figure S2). Pair-fed mice showed the same reduction in liver weight and lipid content as that of butyrate-treated mice (figure 2G,H). Representative pictures of liver sections confirmed that butyrate prevents HFD-induced hepatic steatosis through lowering of food intake (figure 2I).

**Butyrate consumption improves lipid and glucose metabolism, in part by reduced food intake**

Butyrate supplementation significantly decreased plasma TG levels (figure 3A), tended to decrease plasma glucose levels (P=0.05; figure 3B) and markedly decreased fasting insulin levels (figure 3C) and homeostatic model assessment of insulin resistance (HOMA-IR) (P<0.05; figure 3D). The number of c-FOS-positive neurons within the arcuate nucleus in the hypothalamus (B) and nucleus tractus solitarius (NTS) and dorsal vagal complex (DVC) in the brainstem (E) was quantified. The colocalisation percentages of NPY/c-FOS-positive neurons (C) and POMC/c-FOS-positive neurons (D) were quantified, with representative pictures as shown. Data are means±SEM (n=8–9); *P<0.05, ***P<0.001 compared with control group. NPY, neuropeptide Y; POMC, pro-opiomelanocortin.
resistance (figure 3D) as compared with controls, indicating that butyrate improves plasma lipid metabolism and insulin sensitivity. The beneficial effects of butyrate on plasma TG and glucose metabolism could be only partially attributed to the reduced food intake by butyrate, as pair feeding only reduced the plasma glucose level, and had no effects on plasma levels of TG and insulin (figure 3B).

To determine the organs involved in the TG and glucose lowering effects of butyrate, we injected mice with $[^{3}H]$TO-labelled TRL-like particles and $[^{14}C]$DG. In parallel with a decreased plasma TG level, butyrate accelerated the clearance of $[^{3}H]$TO from the circulation as evidenced by reduced half-life of $[^{3}H]$TO (figure 3E). The accelerated $[^{3}H]$TO clearance was caused by a large increase in the uptake of $[^{3}H]$TO-derived...
activity by BAT depots (+174% for interscapular BAT (iBAT) and +123% for subscapular BAT; figure 3F), and to some extent by muscle and WAT (figure 3F). In contrast, food restriction per se by pair feeding did not increase the uptake of [3H]TO-de-derived activity by BAT, muscle and WAT as compared with the control group. As may be expected, both butyrate treatment and pair feeding reduced the half-life of [3H]TO (E) and [14C]DG (G) by various tissues was assessed. Data are means±SEM (n=8-9); *P<0.05, **P<0.01, ***P<0.001 as control group compared with butyrate group; #P<0.05, ##P<0.01, ###P<0.001 as pair-fed group compared with butyrate group. gWAT, gonadal white adipose tissue; iBAT, interscapular brown adipose tissue; sBAT, subscapular brown adipose tissue; sWAT, subcutaneous white adipose tissue; TG, triglyceride.

**Figure 3** Butyrate consumption improves lipid and glucose metabolism, partially by reducing food intake. After 9 weeks of treatment with butyrate, plasma was assayed for TG (A), glucose (B) and insulin (C), and homeostatic model assessment of insulin resistance (HOMA-IR) (D) was calculated. At the end of this study, a combined TG and glucose clearance test was performed. Conscious mice were intravenously injected with [3H] TO-labelled TRL-like particles and [14C]DG. Subsequently, the plasma half-life of [3H]TO (E) and [14C]DG (G) was calculated, and 15 min after injection, the uptake of [3H] (F) and [14C] (H) by various tissues was assessed. Data are means±SEM (n=8-9); *P<0.05, **P<0.01, ***P<0.001 as control group compared with butyrate group; #P<0.05, ##P<0.01, ###P<0.001 as pair-fed group compared with butyrate group. gWAT, gonadal white adipose tissue; iBAT, interscapular brown adipose tissue; sBAT, subscapular brown adipose tissue; sWAT, subcutaneous white adipose tissue; TG, triglyceride.

Butyrate consumption promotes fat oxidation at the expense of carbohydrate oxidation

Since the effects of butyrate on body fat and lipid metabolism could only be partly attributed to reduction of food intake, indirect calorimetry was performed to determine the effects of butyrate on energy expenditure. In the first week of the intervention, when body weight of the mice was still comparable between the butyrate and control groups, mice were housed in fully automated metabolic cages. Butyrate treatment did not affect the spontaneous physical activity of the mice (figure 4A). Although no effect on total energy metabolism was detected (figure 4B), butyrate significantly decreased the respiratory exchange ratio during daytime (figure 4C). This was reflected by an increase in fat oxidation (figure 4D), mostly at the expense of carbohydrate oxidation (figure 4E) during daytime.

**Butyrate consumption increases BAT thermogenic capacity and sympathetic outflow towards BAT**

Next we followed up on the stimulating effect of butyrate on [3H]TO uptake by BAT and fat oxidation by studying BAT in more detail. Butyrate markedly decreased the weight of the iBAT pad (figure 5A), accompanied by a decrease in intracellular lipid vacuole content as compared with the control mice (figure 5B,E). The protein content of uncoupling protein (UCP)-1 per area of BAT was increased (figure 5C,E), suggesting increased thermogenic capacity of BAT. Furthermore, butyrate increased sympathetic outflow towards BAT, as evidenced by increased
protein expression of tyrosine hydroxylase (TH), a marker of sympathetic nerve activity (figure 5D,E). As compared with the pair-fed group, butyrate-treated mice still showed reduced iBAT pad weight (figure 5A), intracellular lipid content (figure 5B) and increased UCP-1 protein content (figure 5C), suggesting butyrate consumption improves BAT thermogenic capacity only partly via a reduction in food intake.

In both subcutaneous WAT and gWAT, butyrate did not induce mRNA expression of the beige adipocyte markers Ucp-1 and Cidea (online supplementary figure S3A,B). Furthermore, we could not detect any UCP-1 protein expression in either WAT depot, suggesting that butyrate treatment does not induce browning of WAT.

The gut-brain neural circuit is necessary for the butyrate-induced satiety and BAT activation

To further investigate the mechanistic involvement of the gut-brain neural circuit in the beneficial effects of butyrate on energy metabolism, we performed the subdiaphragmatic vagotomy and sham surgery, followed by a dietary butyrate intervention for 7 weeks. Again, in the sham-operated group, butyrate reduced cumulative food intake (online supplementary figure S2A) as well as average food intake per se (online supplementary figure S2B) during the 7-week intervention period, and accelerated the clearance of [3H]TO from the circulation (online supplementary figure S2C) as well as increased the uptake of [3H]TO-derived activity by BAT (online supplementary figure S2D). Also, in mice receiving sham surgery, butyrate reduced iBAT pad weight (online supplementary figure S2E) most likely due to a decrease in intracellular lipid vacuole content (online supplementary figure S2F) and enhanced BAT thermogenic capacity as shown by an increased UCP-1 protein content (online supplementary figure S2G). However, after the subdiaphragmatic vagotomy, butyrate treatment also did not influence the clearance of [3H]TO from the circulation.
Gut microbiota

Butyrate consumption alters gut microbiota composition

To investigate whether dietary butyrate affects the composition of gut microbiota, total bacterial DNA was isolated from the cecum content of sham-operated mice and vagotomised mice, after 7 weeks of butyrate treatment. The 16S rRNA gene was sequenced using the MiSeq platform. In sham-operated mice, dietary butyrate did not influence the number of observed species and the Shannon diversity index of the gut microbiota (figure 7A). However, unweighted UniFrac distance analysis showed a clear separation between control mice and butyrate-treated mice (figure 7B). As compared with control mice, butyrate-treated mice had a relative increased abundance of the phylum Firmicutes at the expense of Bacteroidetes (figure 7C).

Linear discriminant analysis effect size indicated that genera belonging to the phylum Firmicutes, class Erysipelotrichi were significantly increased in butyrate-treated mice (figure 7D,E). Interestingly, in vagotomised mice, dietary butyrate significantly increased the number of observed species and the Shannon diversity index of the gut microbiota (online supplementary figure S5A). Unweighted UniFrac distance analysis showed a moderate separation between control mice and butyrate-treated vagotomised mice (online supplementary figure S5B). Similar to the effect in non-vagotomised mice, butyrate also increased the relative abundance of the phylum Firmicutes (online supplementary figure S5C), with even more classes affected, including Erysipelotrichi, Clostridia and Bacilli (online supplementary figure S5D,E). Collectively, our data clearly indicate that dietary butyrate alters the caecal microbiota composition, and in particular increasing the abundance of the phylum Firmicutes, independent of the presence of an intact gut-brain neural circuit.

**DISCUSSION**

Previous findings showed that both dietary administration of butyrate\(^{13,24}\) and stimulation of intestinal butyrate production via probiotics\(^{25,26}\) exert multiple beneficial effects on non-alcoholic...
Gut microbiota

...fatty liver disease and energy metabolism. However, the mechanisms underlying the regulation of energy homeostasis by butyrate are still under debate. In this study, we showed that butyrate reduces food intake. This effect contributes dominantly to the various metabolic benefits of butyrate, including preventing HFD-induced obesity, fat mass gain and hepatic steatosis, and improving hyperglycaemia and insulin resistance. In addition, butyrate also modestly promotes the oxidation of TG, likely by enhancing TG uptake by BAT activation during daytime.

In the search for mechanisms underlying the beneficial effects of butyrate on metabolism, we first demonstrated that both acute and chronic butyrate administration reduce food intake. Previous preclinical studies and clinical studies have demonstrated that administration of dietary fibre, a main resource for intestinal SCFA production by the gut microbiota, increases satiety and decreases energy intake, accompanied by increased endogenous butyrate production. However, the effect of butyrate per se on satiety was still under debate. den Besten et al showed that 5% butyrate (w/w) incorporated into an HFD, in which 45% of calories were from palm oil fat, did not alter food intake in mice. In contrast, Lin et al reported that 5% butyrate incorporated into another type of HFD in which 60% of calories were derived from lard and soybean oil, led to a 22% reduction in cumulative...

Figure 6  The gut-brain neural circuit is necessary for the butyrate-induced satiety and brown adipose tissue (BAT) activation. Mice were individually housed and received the subdiaphragmatic vagotomy surgery. One week after the surgery, mice were fed a high-fat diet (HFD) without (denervation control) or with 5% (w/w) sodium butyrate (denervation butyrate) for 7 weeks. Food intake was measured weekly and cumulative food intake (A) and average food intake per se (B) were calculated. At the end of this study, a triglyceride (TG) clearance test by intravenous injection of [3H]TO-labelled TRL-like particles was performed. The clearance of [3H]TO from the circulation (C) and uptake of [3H] by various tissue (D) was assessed. The weight of iBAT pad (E) was measured and the lipid content within the iBAT was quantified after the H&E staining (F). The protein expression of UCP-1 in iBAT was quantified after immunohistochemistry (IHC) of UCP-1 (G). Data are means±SEM (n=8–9); #P<0.05 compared with denervation control. gWAT, gonadal white adipose tissue; iBAT, interscapular BAT; sBAT, subscapular BAT; sWAT, subcutaneous white adipose tissue; UCP, uncoupling protein.
food intake over 9 days. We confirmed this finding by using the same lard fat in the diet, showing that 5% butyrate supplementation reduces cumulative food intake by 22% over a 9-week intervention period, without influencing spontaneous physical activity of the mice. These data suggest that butyrate unlikely induces systemic toxicity and abnormal motor and behaviour at this dose. Further behavioural assays, including the conditional aversion assay, would be needed to firmly establish whether mice have aversion to butyrate due to its odour and/or taste. The discrepancy between studies may be attributed to the fact that the different dietary fat and carbohydrates distinctly impact the composition of the gut microbiota as well as the production of endogenous SCFAs, especially butyrate,\textsuperscript{29} therefore interfering with the satiety effect induced by exogenous butyrate. Of note, in chow-fed mice, butyrate administration via intragastric gavage rapidly induces satiety and prevented refeeding after an overnight fast. This finding suggests that independent of dietary composition and intestinal SCFAs, butyrate \textit{per se} induces satiety and reduces cumulative food intake.

The GI tract is intimately connected to the central nervous system (CNS) mainly via hormonal and neuronal pathways, with the vagal nerve as the key neural connection between the GI tract

\textbf{Figure 7} Butyrate consumption alters gut microbiota composition. After 7 weeks of intervention, total bacterial DNA was isolated from the caecum content and 16S rRNA genes were sequenced. (A) The number of observed species and the Shannon diversity of the gut microbiota. (B) Principal coordinates analysis plot of unweighted UniFrac distances. Composition of abundant bacterial phyla (C), cladogram generated from linear discriminant analysis (LDA) effect size (LEfSe) (D) and the LDA score (E) showing the most differentially significant abundant taxa enriched in microbiota from the control (red, n=8) and butyrate (green, n=9) group.
and the CNS.10 Our findings that reduced food intake coincided with reduced orexigenic NPY neuron activity in the hypothalamus, and decreased neuron activity within the NTS and DVC in the brainstem, indicate that the effect of butyrate on satiety is likely mediated via vagal inputs to NPY neurons. Indeed, we observed that subdiaphragmatic vagotomy completely abolished the butyrate-induced satiety. It is known that the central terminals of vagal nerve innervate the brainstem, where vagal nerve transmission such as energy status signal projects to the hypothalamus, thereby forming a circuit to regulate satiety.11 Due to our finding that direct intravenous infusion of butyrate did not affect food intake, hypothalamic neuronal sensing of energy status might be a primary target for butyrate supplementation.

On the other hand, the GI tract releases a number of gut hormones, including glucagon-like peptide 1 (GLP-1), which primarily acts on the vagal nerve and also travels through the circulation to directly act on the hypothalamus to regulate satiety signalling. In fact, several studies showed that oral butyrate has the capacity to stimulate GLP-1 secretion.12–13 Convincing evidence shows that GLP-1 receptor activation in vagal afferents14 regulates food intake and energy metabolism. Collectively, it is tempting to speculate that butyrate consumption stimulates GLP-1 secretion from L cells of the GI tract, which activates GLP-1 receptor signalling in the vagal nerve and consequently induces hypothalamic satiety signalling. In addition, another important function of the gut-brain neural circuit is to regulate the intestinal transit,15 which plays an important role in nutrient harvest, thereby directly influencing host energy metabolism. A previous study has shown that butyrate increases colonic motility.16 This may contribute to the metabolic benefits of butyrate by reducing nutrient absorption. Furthermore, Wichmann et al demonstrated that gut microbiota regulate intestinal transit via modulating GLP-1 production.17 In the present study, it remains to be determined to what extent intestinal transit time and motility play a role in the beneficial effects of butyrate. By adding a pair-fed group, we could show that the reduced food intake is the dominant mechanism responsible for multiple distal beneficial effects of butyrate, including preventing diet-induced hepatic steatosis and hyperglycaemia. The effects of butyrate on body weight and fat mass gain, plasma TG and insulin sensitivity were only partly (60%–70%) explained by reduction of food intake.

In addition to inducing satiety, butyrate also promoted the oxidation of fatty acids at the expense of carbohydrates, in particular during conditions of reduced feeding at daytime. An increase in fatty acid oxidation is characteristic for BAT activation18 and we have previously reported a similar metabolic shift from glucose to lipid oxidation after central administration of the GLP-1 receptor agonist exendin-4.19 Therefore, it was not unexpected to find that butyrate accelerates the clearance of plasma TG by activated BAT. BAT functionality is primarily driven by hypothalamus via the action of the SNS.5 We speculate that dietary butyrate reaching the GI tract most likely activates the gut-brain neural circuit, thereby stimulating hypothalamic control of the SNS outflow towards BAT. Consequently, butyrate activates BAT and increases oxidation of intracellular fatty acids resulting in a compensatory influx of TG-derived fatty acids. In fact, butyrate increased in BAT the protein level of TH, which is a marker of SNS activity.20 In vagotomised mice, butyrate failed to increase the uptake of TG-derived fatty acids by BAT, the utilisation of lipid in BAT as well as the protein level of UCP-1, a positive marker for BAT activation. Butyrate also increased the flux of TG-derived fatty acids and glucose into WAT, at least per gram tissue, but did not induce browning of WAT. Since butyrate markedly decreased the size of adipocyte in WAT (online supplementary figure S3C,D), thereby increasing the number of adipocytes per gram tissue, butyrate probably does not affect the uptake capacity of white adipocytes per se. Although the relative volume of BAT in humans may be limited compared with skeletal muscle, the uptake of fatty acids per gram tissue by BAT exceeds that by skeletal muscle by >10-fold (figure 3F). Also, a recent paper redefined whole-body BAT distribution in humans and concluded that its metabolic capacity is substantially higher than usually reported.21 The effects of butyrate on fatty acid uptake and oxidation by BAT we observe in mice may thus well be relevant for humans.

In addition to butyrate, administration of other SCFAs has been reported to induce satiety.41,42 Like butyrate, propionate induces satiety in ruminants probably also via the action of the vagal nerve,43 while acetate may directly regulate hypothalamic satiety signalling after crossing the blood–brain barrier.44 Notably, a recent study showed that an increased production of intestinal acetate due to a high-fat-diet feeding led to the development of obesity and insulin resistance through activation of the vagal nerve.45 This suggests that dietary acetate acts differently on energy metabolism compared with acetate derived from intestinal bacteria fermentation. In this study, dietary butyrate clearly altered the caecal microbiota composition and increased the abundance of the phylum Firmicutes. Previously, increased abundance of the phylum Firmicutes has been associated with a less beneficial metabolic profile.46 However, the specific species amplified within this phylum by butyrate may beneficially affect host energy metabolism. Future studies are needed to investigate the specific contribution of the altered gut microbiota to the beneficial effects of butyrate on host energy metabolism, for example, via faecal microbiota transplantation.

Undoubtedly, weight loss-enhancing strategies are among the most effective interventions for obesity-related diseases, that is, diabetes and cardiovascular disease. Body weight loss can be achieved by decreasing energy intake, that is, decreasing the consumption or absorption of food, and/or by increasing energy expenditure. Although bariatric surgery results in clinically significant weight loss and other beneficial effects, it suffers from a number of adverse events, including surgical complications, perioperative technical outcomes and mortality.46,47 Several antiobesity agents have been developed and are clinically applied with significant benefits, but do have a high probability of developing adverse effects, in particular in the application for long-term weight management.10 Butyrate is currently widely emerging as a potential strategy for treatment of cancer, IBD, inherited disorders and neurodegeneration.48 Our collective data now show that butyrate also induces sustained satiety and enhances fat oxidation, thereby effectively preventing diet-induced obesity, insulin resistance, hypertriglyceridaemia and hepatic steatosis, without inducing any apparent unfavourable effects. Therefore, we propose oral butyrate administration as a promising strategy to combat obesity and related cardiometabolic diseases.
