However, the effects and mechanism of LGG on bowel function remains unclear. 5-Hydroxytryptamine4 Receptor is a critical receptor relating to the intestine motility and secretion function. In this study, we aimed to investigate whether LGG could improve the defecation function via upregulating 5-HT4R and modulating gut microbiota in mice.

**Methods** Male C57BL/6 mice 6–8 weeks in age were randomly divided into 3 groups: MRS group (n=10), Tegasromide group (positive control, n=15) and LGG group (n=15), and MRS broth, tegasromide maleate and LGG supernatant were gavaged respectively for 7 days. YAMC cells and Caco2 cells were used for experiment in vitro. Defecation parameter including the number of pellets in 2 hours, fecal weight, fecal dry weight, fecal water content, and the gastrointestinal transit time (GITT) were detected. PAS and AB-PAS staining were used to evaluate goblet cell numbers in mice colon, and 5-HT4R and MUC2 expression were determined both in vitro and in vivo. Gut microbiota and short-chain fatty acid were analyzed by 16 sRNA pyrosequencing analysis and gas chromatography method.

**Results** The number of defecation pellets in 2 h, fecal weight, fecal dry weight and fecal water content in the Tegasromide group and LGG group were significantly increased compared with those in the MRS group, PAS staining showed that the average number of goblet cells in Tegasromide group and LGG group were significantly increased in mice colon sections compared with MRS group. AB-PAS showed increased cavitated goblet cells in the LGG group, and the mRNA and protein levels of 5-HT4R and MUC2 were upregulated both in vitro and in vivo. In this study, increased levels of Alstistes, Allobaculum, and Desulfovibrion were found in the LGG group which have been reported to be involved in intestine motility, intestinal barrier.

**Conclusions** LGG supernatant could improve defecation function in mice accompanied by upregulating 5-HT4R and MUC2 production, and modulating gut microbiota. Thus, this study will provide a better understanding of probiotics for the prevention and treatment of constipation.
Long non-coding RNA TMPO-AS1 regulates oesophageal squamous cell carcinoma metastases through activating GLI1 by maintaining LAP2a expression

Background Long non-coding RNAs (lncRNA) have been found to play important regulatory roles in cancer development and progression. However, functional lncRNAs and their downstream mechanisms remain largely unknown of oesophageal squamous cell carcinoma (OSCC) metastases. We aimed to identify lncRNAs that regulate OSCC metastases and investigate their downstream mechanisms.

Methods Small interfering RNA library was built of the top 50 overexpressed lncRNAs in OSCC according to TCGA database. Transwell migration assay was performed to identify the lncRNA that markedly affected cell migration. TMPO-AS1 expression was validated by qPCR in patient tissues and OSCC cell lines. Gain and loss of function of TMPO-AS1 were performed in transwell migration and invasion assays in vitro. Lung and lymph node metastases models were built with short hairpin RNA knockdown in vivo. RNA pull-down and RNAase protection assay (RPA) followed by qPCR analysis identified the RNA-RNA interaction. Downstream mechanisms were examined by regular molecular biological methods.

Results We identified TMPO-AS1 as a key regulator of OSCC metastases. TMPO-AS1 expression was upregulated in OSCC tumor tissues compared to adjacent normal tissues and positively correlated with the mRNA expression of TMPO (LAP2a), its sense coding gene. Knockdown of TMPO-AS1 significantly inhibited OSCC cells migration and invasion in vitro and attenuated metastases in two different animal models in vivo. Overexpression of TMPO-AS1 showed contrary effects. RNA pull-down identified the interaction between TMPO-AS1 mRNA and LAP2a mRNA. RPA assay further confirmed TMPO-AS1’s protective effect on LAP2a mRNA. Western blotting found that knockdown of TMPO-AS1 decreased the expression of LAP2a without affecting LAP2b. Ectopic expression of LAP2a after TMPO-AS1 knockdown rescued the adverse effect on cell migration and invasion. By regulating the expression of its sense coding gene LAP2, TMPO-AS1 maintained the levels of LAP2a, which in turn activated Hedgehog signaling transcription factor GLI1 and its downstream target SNAIL1, therefore promoting OSCC progression.

Conclusions TMPO-AS1 acts as an essential regulator in OSCC metastases by interacting with LAP2a mRNA and maintaining its levels, which activates the LAP2a-GLI1-SNAIL1 axis and facilitates OSCC metastases.

THE LANDSCAPE OF RECURRENT NONCODING MUTATIONS IN COLORECTAL CANCERS

1Nurul-Syakima Ab Mutalib*, 1Raja Ilani Mohd Yusuno, 1Najwa Farah Mohd Yusof, 1Muhiddin Ishak, 1Sazuta Saidin, 2Isa Mohamed Rose, 3Luqman Mdzlan, 3Ismail Sapag, 1Rahman Jamal. 1UKM Medical Molecular Biology Institute (UMBI), National University of Malaysia, Malaysia; 2Department of Pathology, Faculty of Medicine, National University of Malaysia, Malaysia; 3Department of Surgery, Faculty of Medicine, National University of Malaysia, Malaysia

Background Colorectal cancer (CRC) is among major cancer worldwide, and it has become evident that the identification of driver mutations is fundamental to understanding carcinogenesis. Although genes frequently mutated in CRC have been identified, those pursuits for driver mutations have mainly focused on the coding genome. The noncoding somatic mutation landscape remains unexplored. Hence, this study aims to characterize the landscape of noncoding somatic mutations in CRC.

Methods Genomic DNA was extracted from 36 cancerous colonic tissues and subjected to whole genome sequencing (WGS). Blood DNA served as the germline control. The sequencing data were aligned to hg19 using Burrow-Wheeler Aligner (BWA), somatic variants were called using muTect2 and the noncoding mutations were prioritized using funseq2. Pathway enrichment analysis was performed using DAVID, and gene expression data were retrieved from Firebrowse.

Results We identified 72,890 recurrent noncoding alterations, which were altered in at least 2 patients. Focusing on the distal regulatory modules (DRMs), the majority (8.2%) of the alterations were identified in transcription factor binding peaks (TFP), followed by Segway/ChromHMM-predicted enhancers (8.39%) and DNase I hypersensitive sites (DHS) (3.68%). In addition, 0.56% alterations were discovered in the long intergenic noncoding RNAs (lincRNAs) and 0.02% in transcription factor bound motifs in peak regions (TFM). MAFK chr:50489–63382 and WRNIP1[chr6:292554–300830 are the most frequently altered TFPs (9/36), while drm chr17:21514800–21518300 is the most frequently altered enhancers (8/36). There was a modest upregulation of MAFK (log2 RSEM = 0.997) and WRNIP1 (log2 RSEM = 1.45) gene expression in cancer compared to the normal based on 626 CRCs from COADREAD TCGA dataset. LineRNA (ENSNG00000238261.3[BX004987.5]) alteration was identified in 8/36 of patients. We also show the commonality of pathways targeted by coding and noncoding mutations, demonstrated by TP53, APC, and KRAS, which regulates Wnt and MAPK signaling, the crucial pathways in colorectal carcinogenesis.

Conclusions This study provides an enhanced understanding of colorectal carcinogenesis and describes the advantages of...
