Background The growth tendencies of abdominal tuberculosis have increased more than twice between the year 2006–2016, and primarily associated, with an increase in the number of HIV-positive individuals. The most formidable and most frequent complication of tuberculosis of the abdominal cavity is perforation of specific ulcers of the intestine.

Methods Was to evaluate the results of surgical management of patients with perforated tuberculosis ulcers of the intestine against the background of late-stage of HIV infection and to develop optimal surgical tactics for this category of patients. 149 patients with perforated tuberculosis ulcers of the intestine underwent surgical treatment at the surgical department of our clinic in the period of time between the year 2006 and 2016.

Results Ulcerative lesions of intestine were detected in all cases during laparotomy, single and multiple ulcers were located in the jejunum, iliac or cecum, more often affecting the ileocecal zone. The most optimal method of surgical management of perforated ulcers of the intestine in patients with the late stages of HIV infection is performing a resection of the affected portion of the intestine with the construction of delayed anastomosis.

Conclusions A resurgence in tuberculosis during the HIV era produces a new spectrum of presentations for the surgeon. Avoidance of construction of primary anastomosis, as well as direct visual control during laparotomy, allows timely detection and elimination of new perforations, as well as evaluation of treatment effectiveness.

(Figure 1)
which proved prevalence are different depending on race (10.35% Asian vs 1.51% White; \( P = 0.027 \)).

**Conclusions** We firstly report primary sites and racial heterogeneity of POLE/POLD1 mutation in CRC to call for more attention when designing clinical trials and data analysis.

**TO COMPARE THE TISSUE DIAGNOSTIC YIELD OF SOLID LESION BIOPSIES BASED ON THE HISTOPATHOLOGICAL ANALYSIS OF ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION (EUS–FNA) SAMPLES PRODUCED BY THE 19G PROCORE NEEDLE, STANDARD 19G NEEDLE AND 22G PROCORE NEEDLE**

**Background** EUS is a sensitive method for detecting intestinal and extra-intestinal mass lesions including lymphadenopathy. FNA allows evaluating cellular findings suggestive of malignancy but inflammation causes cellular changes undistinguishable from neoplasm solely based on the cytological evaluation, because tissue architecture and cell morphology are essential for accurate pathological assessment. Various EUS-guided techniques have been explored to retrieve tissue specimens with variable success and complication rates.

**Methods** All the Patients, above 18 years of age, having intestinal and extra-intestinal solid mass lesions including lymphadenopathy, were subjected to EUS guided FNA. Patients with cystic lesions refused to sign the informed consent and with coagulopathy (INR>1.5, Platelets <50000) were excluded from the study.

**Results** Total 215 patients were evaluated, out of which EUS-FNA was technically feasible in 210 (97.67%) cases. Three needle passes were made in every case. There was no significant difference between these three groups with regard to the age (p-value-0.676), gender (p-value-0.856), location (p-value-0.998), echogenicity (p-value-0.123), border (p-value-0.216), size (p-value-0.735 & 0.374) of the lesions and presence of calcification (p-value-0.093) or necrosis (p-value 0.729). Sample suitable for pathological evaluation was obtained in 90.5% cases with a tissue core in 45.7% cases. 28.1% lesions were malignant, 62.4% were benign and 9.5% remained undiagnosed. The histopathological diagnoses were possible in 87.1%, 90.0% and 94.3% cases respectively with 22G Procore, 19G Procore and 19G Standard needles (p-value-.350). Samples for the presence of blood clot in order of 19G procore (70.00%) > 22G procore (50.00%) > 19 G Standard (42. 8%),(P-value 0.003). There were no post-procedure complications noted in any group.

**Conclusions** Procore needles did not offer the extra possibility of obtaining a core sample for histopathological analysis in this study, but there is a high possibility of the presence of blood clots. Any of these three needles can be used for biopsy according to the availability and expertise of the endosonologist. The outcome depends on the experience of the endosonologist as well as the pathologist.

10.1136/gutjnl-2020-IDDF.49

**Background** It is confirmed that patients’ prognosis of pancreatic neuroendocrine tumors (pNETs) were different according to different pathological grades. Imagings may predict tumor grades. We intended to analyse the value of contrast-enhanced ultrasound (CEUS) in the pathological classification of pNETs.

**Methods** Eighty-six pNETs patients who underwent CEUS before pathologic diagnosis were retrospectively reviewed. Ultrasonographic features and enhancement pattern in each phase were analyzed among the three pathologic grades of pNETs.

**Results** Eighty-six pNETs included 45 G1(52.3%), 29 G2 (33.7%), 12 G3 (14.0%). 48.9% (22/45) G1 tumors were less than 2 cm, while 93.1% (27/29) G2 and 100% (12/12) G3 were larger than 2 cm (G1 vs. G2, \( p < 0.001 \); G1 vs. G3, \( p = 0.001 \). 58.3% (7/12) G3 tumors had pancreatic duct dilatation and 41.7% (5/12) G3 had hepatic metastasis, which were more common than G1 tumors with both only 4.4% (2/45) had pancreatic duct dilatation or hepatic metastasis (p < 0.001, p = 0.002). On CEUS, G1 tumors ((figure 1A,1B) showed homogeneously hyper-enhancement in the early phase) more often manifested hyper- or iso- enhancement in the
