reduction. Fourteen (13%) children with failed reduction underwent laparotomy. Twelve of these fourteen children had to undergo bowel resection (seven gangrene and five lead points) and the rest two had a successful operative reduction. Two (2%) children with perforation following reduction, a child (1%) each with doubtful reduction and doubtful pneumoperitoneum underwent surgery. Seven (8%) of 89 successful reductions had a recurrence. The management of these children is depicted in figure 1.

A higher rate of failed reduction was found in children who presented at or after 48 hours of the onset of symptoms (p<0.03) and abdominal distension at presentation (p<0.002). On multiple logistic regression analysis, the children presenting at or after 48 hours onset of symptoms (OR: 11.3/p-0.039) and abdominal distension at presentation (OR: 4.46/p-0.021) were found to be associated with increased risk of failure of non-operative reduction. The variables age <1 year (OR:0.466/p-0.165), weight <10 kg (OR: 1.641/p-0.468), pain abdomen (OR: 1/p-0.99), vomiting (OR: 0.562/p-0.39), bilious vomiting (OR: 6.75/p-0.136), fever (OR: 2.23/p-0.357), bleeding per rectum (OR: 2.55/p-0.162), and palpable mass (OR: 2.74/p-0.135) were not associated with the failed non-operative reduction.

Conclusions The risk factors for failed non-operative reduction of intussusception include a presentation at or after 48 hours of the onset of symptoms and the presence of abdominal distension at presentation.

**Background** Patients with gastric cancer usually have weight loss, sarcopenia and malnutrition. Serum creatinine/cystatin C (CCR) is a new, simple, easily measured tool that could serve as a biomarker of sarcopenia. The purpose of our study was to assess the predictive ability of preoperative CCR for short-term prognosis in patients with gastric cancer undergoing surgery.

**Methods** This retrospective study included 309 patients with gastric cancer undergoing surgery. Univariate and multivariate analyses were performed to identify risk factors. Patients were divided into two groups according to the optimal cut-off value of CCR. The clinical association of CCR with characteristics and postoperative complications was evaluated.

**Results** Among all the patients, age, lymphocyte count and cystatin C (CysC) level were independent risk factors, while red blood cell (RBC) count and CCR were independent protective factors for short-term postoperative
Complications in gastric cancer patients undergoing surgery. The preoperative CCR showed a good predictive ability for short-term postoperative complications, with an optimal cut-off value of 7.117. Patients with low CCR had a higher incidence of overall complications (P<0.001), including mild complications (P<0.001) and major complications (P<0.001).

Conclusions The preoperative CCR was identified as a reliable nutrition and sarcopenia assessment tool for predicting short-term prognosis for patients with gastric cancer after surgery.

Background Frailty has been described in young patients with chronic inflammatory conditions. We aimed to determine the prevalence and impact of frailty among inflammatory bowel disease (IBD) outpatients.

Methods Patients were prospectively recruited from our tertiary IBD clinic Nov 2018–Nov 2019. Frailty was defined by Fried Frailty Index (FFI). Crohn’s Disease Activity Index (CDAI) for Crohn’s disease (CD) or partial Mayo score for ulcerative colitis (UC) and IBD unclassified (IBDU). IBD questionnaires (IBDQ), Patient Health Questionnaire-9 (PHQ-9) and Charlson comorbidity index (CCI) were collected.

Results Forty-one patients were recruited (63% female, median age 32, 22% UC, 71% CD, 7% IBDU). Five patients (12%) were frail (FFI>3) and 36 (88%) were non-frail: 20 (49%) pre-frail (FFI=1–2), 16 (39%) robust (FFI=0). Frail patients were older (median age 54 vs. 31, P=0.03) with longer duration of IBD (median 20 vs. 6 years, P=0.05) compared to non-frail. FFI correlated with CCI (Pearson r=0.32, P=0.04). Mean CDAI and median partial Mayo scores were higher in frail/pre-frail patients with CD (224 vs. 112, P<0.01) and UC/IBDU (3 vs. 0.5, P=0.03) compared to robust patients. Conversely, the proportion of frail/pre-frail patients increased with IBD activity: remission (24%), mild (36%), moderate (89%) and severe disease activity (100%), PP=0.02. Compared to robust patients, frail/pre-frail patients had higher mean PHQ-9 scores (11.0 vs. 7.1, P=0.02) and higher depression rates (60% vs. 25% with PHQ-9 ≥ 3, P=0.03). Anti-depressant use increased with FFI score (11% FFI=0, 17% FFI=1, 40% FFI=2, 100% FFI≥3). Frail/pre-frail patients had lower mean IBDQ scores (141 vs. 169, P=0.02) compared to robust patients denoting worse quality of life (QOL).

Conclusions Frailty or prefrailty is common among IBD outpatients and associated with older age, comorbidity, IBD duration, disease activity, prednisone use, depression and lower QOL.
