The yield of colonic investigations following an index episode of acute diverticulitis

Lauren Chong*, Inani Mohit, Abdul Rahman, Jad Alkhoury, Tufail Raza, Srisha Hebbar. University of North Midlands Royal Stoke, Stoke on Trent, UK

Introduction

The practice of undertaking colonic investigations following an index episode of acute diverticulitis is widespread. Recent guidelines suggest that this is not necessary, particularly in patients with uncomplicated diverticulitis. We have evaluated the yield of colonic investigations in patients after an index episode of acute diverticulitis.

Methods

We conducted a retrospective analysis of all patients who were admitted to our tertiary centre with acute diverticulitis between January 2017 and December 2019. All patients who were admitted to our tertiary centre with acute diverticulitis were included. We excluded patients with complicated diverticulitis, patients with symptoms suggestive of diverticulitis who were referred for imaging but did not undergo colonic investigations, and patients with previous CRC.

Results

We identified 602 patients with acute diverticulitis (366 females, mean age 62.4 (SD +/- 14.7 years old) who were admitted to our tertiary centre with acute diverticulitis. Of these, 74.1% of patients (n=446) had uncomplicated diverticulitis and 25.9% (n=156) had complicated diverticulitis. Overall, our study identified key areas of improvement in the current practice.

Conclusions

This argues depleted activity of butyrate-producing bacteria via the major butyrate production pathway is a true signature of CRC.

Conclusions

We show that the taxonomy of active microbiota is not always consistent with abundances established by DNA sequencing, which appear to somewhat overestimate shifts in bacterial populations between homeostasis and disease. These novel data will light the path to targeting microbial gene expression as a means of next-generation therapeutic strategy to combat inflammatory diseases of the gut.
Abstract PWE-53 Figure 1 Plot of constipation admissions against opioid prescriptions between the years 1998-1999 (referred to as above as 1999) and 2017-2018 (2018)

PWE-53 THE RELATIONSHIP BETWEEN HOSPITAL ADMISSIONS FOR CONSTIPATION AND OPIOID PRESCRIBING: A 20 YEAR CORRELATION STUDY

1Shivam Chauhan*, 1,2Maura Corsetti, 1,2Timothy Card. 1University Of Nottingham, Nottingham, UK; 2NIHR Nottingham Biomedical Research Centre at the Nottingham University Hospitals NHS Trust and the University of Nottingham, Nottingham, UK

Background Constipation is a common problem with numerous causes, including several drugs among which opioids are prominent. Considering the reported increase in opioid prescriptions worldwide, we hypothesised that if this is mirrored in England then hospital admissions for constipation would rise in proportion to the rise in opiate prescriptions.

Methods Publicly available data on admissions was obtained using NHS Hospital Admissions Statistics and data on opioid prescribing using NHS Prescription Cost Analysis. Admissions and opioid prescriptions were summarised annually, and the changing age structure of the population measured as the proportion over 75 between 1998 and 2020. Annual opioid prescriptions were plotted against annual admissions for constipation and the data modelled using Poisson regression to correct for the effect of changing population structure.

Results Between 1998 and 2018, opioid prescribing increased by a factor of 5 and constipation admissions have increased across age groups except (0-14). Patients are spending less days in hospital (declining from a mean of 5 to 3 days) per admission with the overall number of bed days remaining relatively consistent over the past 20 years. The English population has become more elderly with the proportion over 75 years of age increasing. A plot of opioid prescriptions against admissions for constipation confirms that they rise together (Figure 1). Poisson regression shows that admissions rise with an incidence rate ratio of 1.025 (95% CI 1.024-1.026) for every million extra prescriptions after correcting for the aging population.

Discussion The findings demonstrate a clear association between opioid prescribing and constipation in England over the last 2 decades. We are unable to correct for the effect of most potential confounders, although we have attempted to address the possible effect of an aging population. The ecological nature of the study in addition precludes us attributing causality to the association. However, the strength of the relationship, the biological plausibility of the mechanism and the importance of the problem, mean this needs to be investigated further.

PWE-54 TRANSDUODENAL SPHINCTEROPLASTY IN THE MANAGEMENT OF REFRACTORY PAIN IN TYPE II SPHINCTER OF ODDE DISFUNCTION

1Shyam Menon*, 2Ravi Marudanayagam. 1The Royal Wolverhampton NHS Trust, Wolverhampton, UK; 2University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK

10.1136/gutjnl-2021-BSG.317

Introduction The management of Type II sphincter of Oddi dysfunction (SOD) or functional biliary sphincter disorder (FBSD) is complex. Endoscopic biliary sphincterotomy is ineffective in a proportion of patients and many patients continue to experience debilitating attacks pancreaticobiliary pain necessitating multiple hospital admissions. Intermittent intra-sphincteric Botulinum toxin (Botox) injection, in conjunction with neuromodulatory therapy is useful in alleviating pain in many patients with ongoing functional biliary pain1, but some patients develop pain refractory to Botox therapy. Surgical biliary sphincteroplasty has been previously demonstrated to be effective in the management of SOD.2 We present our experience in managing refractory pancreaticobiliary pain in FBSD by surgical sphincteroplasty.

Methods A retrospective review of case notes over a 7-year period (2013-2020) was performed. The diagnosis of Type II SOD or FBSD was made in post cholecystectomy patients with abdominal pain identical to their pre-cholecystectomy pain. All patients underwent extensive investigations including blood tests, gastroscopy, trans-abdominal ultrasoundography, cross-sectional imaging with MRCP or CT and endoscopic ultrasound and Morphine TBIDA scans. Patients with typical pre-cholecystectomy pain and either a dilated bile or anormal liver function tests (ALT or ALP x 1.5 times upper limit of normal) in line with the modified Milwaukee criteria and/or a positive Morphine TBIDA scan were identified as Type II SOD or FBSD. All patients underwent endoscopic biliary sphincterotomy and due to ongoing pancreaticobiliary pain, underwent intermittent Botox injections, under deep sedation or anaesthesia, in a quadrantic fashion around the sphincterotomised ampullary area. Transduodenal surgical sphincteroplasty was performed in these patients once their pain became refractory to further Botox therapy. The efficacy of surgical sphincteroplasty was recorded at post-procedure outpatient review using a nominal pain scale. The need for opioid analgesia and adjustments to neuromodulatory medication were recorded on follow up.
