**ABSTRACT**

Objective Using faecal shotgun metagenomic sequencing, we identified the depletion of *Lactobacillus gallinarum* in patients with colorectal cancer (CRC). We aimed to determine the potential antitumourigenic role of *L. gallinarum* in colorectal tumourigenesis.

Design The tumour-suppressive effect of *L. gallinarum* was assessed in murine models of CRC. CRC cell lines and organoids derived from patients with CRC were cultured with *L. gallinarum* or *Escherichia coli* MG1655 culture-supernatant to evaluate cell proliferation, apoptosis and cell cycle distribution. Gut microbiota was assessed by 16S ribosomal DNA sequencing. Antitumour molecule produced from *L. gallinarum* was identified by liquid chromatography mass spectrometry (LC-MS/MS) and targeted mass spectrometry.

Results *L. gallinarum* significantly reduced intestinal tumour number and size compared with *E. coli* MG1655 and phosphate-buffered saline in both male and female murine intestinal tumourigenesis models. Faecal microbial profiling revealed enrichment of probiotics and depletion of pathogenic bacteria in *L. gallinarum*-treated mice. Culturing CRC cells with *L. gallinarum* culture-supernatant (5%, 10% and 20%) concentration-dependently suppressed cell proliferation and colony formation. *L. gallinarum* culture-supernatant significantly promoted apoptosis in CRC cells and patient-derived CRC organoids, but not in normal colon epithelial cells. Only *L. gallinarum* culture-supernatant with fraction size <3 kDa suppressed proliferation in CRC cells. Using LC-MS/MS, enrichments of indole-3-lactic acid (ILA) was identified in both *L. gallinarum* culture-supernatant and the gut of *L. gallinarum*-treated mice. ILA displayed anti-CRC growth in vitro and inhibited intestinal tumourigenesis in vivo.

Conclusion *L. gallinarum* protects against intestinal tumourigenesis by producing protective metabolites that can promote apoptosis of CRC cells.

**Significance of this study**

What is already known on this subject?

⇒ *Lactobacillus gallinarum* is one of the most depleted probiotic species in the stool of patients with colorectal cancer (CRC).

What are the new findings?

⇒ Administration of *L. gallinarum* inhibited colorectal tumourigenesis in *Apc*Min/+ mice and in azoxymethane/dextran sulfate sodium-treated mice.

⇒ *L. gallinarum* increased abundances of gut probiotics and depleted potential gut pathogens.

⇒ *L. gallinarum* culture-supernatant suppressed cell proliferation, and induced apoptosis in CRC cell lines and in organoids derived from patients with CRC.

⇒ Secreted non-protein molecule(s) with a molecular weight <3 kDa from *L. gallinarum* mediated the anti-CRC effect.

⇒ Indole-3-lactic acid, a small molecule with known anti-inflammatory property, was identified as the most enriched metabolite produced by *L. gallinarum*.

How might it impact on clinical practice in the foreseeable future?

⇒ The probiotic *L. gallinarum* is a potential prophylactic for preventing CRC in humans.

INTRODUCTION

Colorectal cancer (CRC) is the third most commonly diagnosed malignancy and the second leading cause of cancer death in the world.1 There are many risk factors associated with CRC carcinogenesis including genetic alterations, lifestyle and environmental factors.2 Over the last decade, gut microbiota has been shown to play a key role in CRC development. Certain probiotic bacteria such as *Streptococcus thermophilus* and *Lactobacillus rhamnosus* have demonstrated anticarcinogenic properties.3 4

Most *Lactobacillus* species are classified as lactic acid bacteria (LAB). LAB are generally found in fermented food, such as decomposing plants and milk products, and they are widely accepted to be used as probiotics for humans.5 The beneficial effects of LAB have been reported extensively6 7 and preclinical studies have shown its abilities to reduce chronic inflammation associated with...
cancer development.8 9 Using shotgun metagenomic sequencing, we identified a probiotic species Lactobacillus gallinarum being significantly depleted in the stool of patients with CRC.10 suggesting that it might play a role in suppressing CRC. In this study, we showed that L. gallinarum could abrogate colorectal tumourigenesis in mouse models, human CRC-derived organoids and CRC cell lines through promoting apoptosis. This tumour-suppressing effect was attributed to indole-3-lactic acid (ILA), a metabolite generated by L. gallinarum.

MATERIALS AND METHODS

Animal experiments

Male and female ApoMin−/− C57B/6 mice, which can faithfully recapitulate the human familial adenomatous polyposis, was used as a mouse model of spontaneous CRC.11 ApoMin−/− mice at 5–6 weeks old were divided into three groups with or without CH-223191 treatment: (1) phosphate-buffered saline (PBS); (2) Escherichia coli MG1655 and (3) L. gallinarum. Lactobacillus casei was further used as a LAB control. L. gallinarum was cultured in MRS broth (Difco Laboratories, Detroit, Minnesota, USA) and L. casei and E. coli MG1655 were cultured in brain heart infusion (BHI) broth. After 1 day, each of the bacteria was collected and resuspended in PBS and then gavaged to mice (1×10⁸ colony-forming unit (CFU)/100μL PBS per mouse). Male and female mice were gavaged once daily for 8 and 12 weeks, respectively, for the development of neoplastic lesions. Body weight and stool were examined weekly.

The azoxymethane (AOM)/dextran sulfate sodium (DSS) model, which can mimic human colitis-associated carcinoma (CAC), was also established. Male and female C57BL/6 mice at 6 weeks old were intraperitoneally injected with a single dose of 10mg/kg AOM (Merck, Darmstadt, Germany), followed by 2% DSS (MP Biomedicals, Solon, Ohio, USA) administration for 1 week. AOM/DSS-induced CRC mice were gavaged with L. gallinarum and E. coli MG1655 suspension following the same schedule.

Mouse colonoscopy (Karl Storz Endoskope, Tuttingen, Germany) was performed prior to sacrifice. The colonoscope was inserted into anus and advanced proximally under direct visualisation, facilitated by air insufflation, and representative pictures of the colon tumour from each group were recorded. After neoplastic lesions developed, mice were anaesthetised and sacrificed. Small intestines and colons of mice were longitudinally opened and rinsed with PBS. Total number of tumours in small intestine and colon were recorded. Size of each tumour was measured using previous published formula.12

16S rDNA gene sequence analysis

Contigs were created using Needleman-Wunsch alignment algorithm with default parameters,14 and aligned against the SILVA database (V.123) using NAST algorithm.15 16 We removed any contigs with homopolymers of >8 nucleotides and retained all that mapped within the identical coordinates. Any sequence pairs with mismatch difference of ≤2 were preclustered to reduce amplicon sequencing noises. Chimeric sequences were culled using de novo UChime.17 Postquality controlled sequences were classified using Greengenes 16S rRNA database (V.13.8). We discarded any sequences of eukaryotic, archaea, mitochondrial, chloroplastic or unknown origins before binning them into operational taxonomic units (OTUs) at 97% identity threshold. The lowest taxonomic annotation for an OTU was defined as having a consensus assignment score of ≥80. Sequence count table was rarefied to the smallest number of reads per sample (ie, 44845 reads) to reduce the effects of variable sequencing depths on downstream analyses. The significance of Alpha diversity was assessed by Wilcoxon rank-sum test. Beta diversity was visualised by principal coordinate analysis. P value <0.05 was considered statistically significant. Differential abundance analysis was performed with one-way analysis of variance (ANOVA). Average fold change for each OTU and heatmap was computed in the R Project for Statistical Computing.18 The p values obtained were adjusted for multiple comparisons by the false discovery rate method. The corresponding q <0.05 was considered statistically significant.

Bacterial strains and culture conditions

L. gallinarum (ATCC 33199) and L. casei (ATCC BAA-2843) were purchased from American Type Culture Collection (ATCC; Manassas, Virginia, USA). E. coli strain MG1655 (ATCC 700926), a non-pathogenic human commensal intestinal bacterium, was included as a negative control.19 They were cultured in MRS broth or BHI broth as appropriate at 37°C under aerobic condition.

CRC patient-derived organoid culture

CRC organoids derived from 2 patients (74 and 816) were obtained from Princess Margaret Living Biobank (Toronto, Ontario, Canada), and embedded into Matrigel (Corning, Corning, New York, USA). Culture medium was changed every 2 days. After 5 days of culture, Matrigel was removed to expose organoids by mechanical stress and/or TrypLE digestion (Sigma-Aldrich). Organoids were then collected for further experiments. The detailed information about these two patients with CRC is listed in online supplemental table 1.

Cell viability assay

Cell viability was measured by 3-(4,5-dimethylthiazoly-2-yl)-2,5-diphenyltetrazolium bromide (MTT) (Sigma-Aldrich) assay. Cells were seeded on 96-well plates at 1.0×10⁴ cells per well and incubated for 24 hours before treatment. Cells were cultured in Dulbecco’s Modified Eagle’s Medium with addition of bacterial supernatants at different concentrations (5%, 10% or 20%) or the same amount of ILA (Sigma-Aldrich) comparable to that of 20% L. gallinarum culture supernatant (LGCS). Cell proliferation was measured by MTT assay for five consecutive days. The amount of MTT formazan product was determined by measuring absorbance at a wavelength of 570 nm (OD₅₇₀) with a microplate reader (Multiskan GO Microplate Spectrophotometer, Thermo Scientific, Vantaa, Finland). For pharmacological inhibition of aryl hydrocarbon receptor (AhR), CH-223191 (100 nm) was added 12 hours before the treatment with bacteria culture supernatant.

Apoptosis assay and cell cycle analysis

Cells were plated on 6-well plates 24 hours prior to treatment, and cultured in medium containing 10% LGCS, E. coli culture supernatant (ECCS) or BHI. CRC patient-derived organoids were cultured on 6-well plates, and 10% LGCS, ECCS or BHI was added to Matrigel and growth medium. After 5 days of treatment, cells and organoids were digested in 0.25% trypsin-EDTA (Gibco-Invitrogen, Grand Island, New York, USA) and TrypLE, respectively. For apoptosis assay, the proportion of apoptotic cells was evaluated by dual staining with Annexin V-PE and 7-aminoactinomycin D (7-AAD) (BD Pharmani, San Jose, California, USA). Combination of Annexin V-PE and

Gut microbiota

Gut: first published as 10.1136/gutjnl-2020-323951 on 22 December 2021. Downloaded from http://gut.bmj.com/ on November 20, 2023 by guest. Protected by copyright.
7-AAD stained distinguished early apoptotic cells (Annexin V+, 7-AAD+) and late apoptotic cells (Annexin V+, 7-AAD-). For cell cycle analysis, cells treated with 1% LGCS, ECCS or BHI for 1 day were fixed and stained with 50 µg/mL propidium iodide (BD Pharmingen). Cell cycle of all stained cells were analysed using FASAría cell sorter (BD Biosciences, San Jose, California, USA).

**Liquid chromatography mass spectrometry (LC-MS/MS)** - tandem mass spectrometry analysis for bacteria culture supernatant

To investigate anti-CRC metabolites in LGCS, 100 µL of each sample (LGCS, ECCS, BHI) was added to 400 µL extraction solution containing internal standard (L-2-chlorophenylalanine, 2 µg/mL). Following centrifugation, 75 µL of supernatant was transferred to a fresh glass vial for liquid chromatography mass spectrometry (LC-MS/MS) analysis. Ultra-high performance liquid chromatography (UHPLC) separation was carried out using a 1290 Infinity series UHPLC System (Agilent Technologies, Palo Alto, California, USA), equipped with a UPLC BEH Amide column. The analysis was carried with elution gradient as follows: 0–0.5 min, >95% B; 0.5–7.0 min, 95%–65% B; 7.0–8.0 min, 65%–40% B; 8.0–9.0 min, <40% B; 9.0–9.1 min, 40%–95% B; 9.1–12.0 min, 95% B. The TripleTOF 6600 mass spectrometry (AB Sciex, Foster city, California, USA) was used to acquire tandem mass spectrometry (MS/MS) spectra on an information-dependent basis during LC-MS/MS experiment. The processing of LC-MS/MS raw data was achieved using R package XCMS (V.3.2). Peak annotation was processed by CAMERA package implemented in the R language. Human MS2 database, Human Metabolome Database (HMDB, www.hmdb.ca), and METLIN metabolite database (metlin.scripps.edu) were used for a more reliable metabolite identification. Significantly enriched metabolites were identified by a two-tailed Mann-Whitney U test. Compared with BHI or ECCS, specific metabolite enriched in LGCS with adjusted p value <0.05 was considered statistically significant.

**Statistical analysis**

Values are expressed as mean±SD for both in vivo and in vitro experiments. Comparisons between two groups were performed using a two-sided Student’s t-test. ANOVA was used to compare differences among multiple groups, and post hoc analysis was performed by Tukey’s multiple comparisons test. P value <0.05 indicates statistical significance. Additional methods are provided in the online supplemental material 1.

**RESULTS**

*L. gallinarum* protects against intestinal tumourigenesis in *Apc*−/− mice

To investigate the effect of *L. gallinarum* on colorectal tumourigenesis, we first used male *Apc*−/− mice. We gavaged the mice with *L. gallinarum* (1.0×10⁸ CFUs per mouse), a non-tumourigenic
E. coli strain MG1655 (1.0×10⁸ CFUs per mouse) as bacteria control, or PBS once daily for 8 weeks (figure 1A). During the period of gavage, there was no difference in body weight among groups (online supplemental figure 1A). The incidence of bloody stool in L. gallinarum group was lower than that of the PBS group (p<0.05) after gavage for 8 weeks (online supplemental figure 1B). Colonoscopy identified that colon tumour sizes in L. gallinarum group were visually smaller than the E. coli MG1655 or PBS groups (figure 1B). After sacrifice (figure 1C), significant reductions in tumour number (E. coli, p=0.034; PBS, p=0.005) (figure 1D) and tumour size (E. coli, p<0.05; PBS, p<0.05). L. gallinarum also significantly decreased tumour number (E. coli, p=0.003; PBS, p<0.05) (figure 1D) and tumour size (E. coli, p=0.0012; PBS, p<0.05) (figure 1E) in the small intestine of ApcMin/+ mice (figure 1F).

To determine if the protective effect of L. gallinarum against CRC is gender-specific, we repeated the experiment in female ApcMin/+ mice (figure 1G). L. casei, a well-known LAB which has been reported to inhibit CRC progression through releasing small molecules,20 was used as a positive control. We observed consistent results as in the male ApcMin/+ mice, including decreased tumour development as captured by colonoscopy (figure 1H) and tumour incidence in colon (figure 1I) and small intestine (figure 1J) in L. gallinarum-treated female ApcMin/+ mice. Significant reductions of both total tumour number (L. gallinarum vs E. coli, p<0.01; L. gallinarum vs PBS, p<0.01) and total tumour size (L. gallinarum vs E. coli, p<0.05; L. gallinarum vs PBS, p<0.05) were also observed in L. gallinarum-treated female ApcMin/+ mice as compared with controls (figure 1K and L, online supplemental figure 2). Accordingly, L. casei slightly inhibited tumour formation in female ApcMin/+ mice (figure 1K), but its effect was not as strong as that of L. gallinarum. These results suggested that L. gallinarum abrogates intestinal tumourigenesis in both male and female ApcMin/+ mice.

L. gallinarum protects against intestinal tumourigenesis in AOM/DSS-induced CRC mice

To validate the tumor-suppressive effect of L. gallinarum on colorectal tumourigenesis, we established a colitis-associated CRC model, in which C57BL/6 mice aged 6 weeks were intra-peritoneally injected with 10 mg/kg AOM, followed by 2% DSS administration for 1 week (figure 2A). L. gallinarum significantly reduced colorectal tumour number (E. coli, p<0.05; PBS, p=0.007) and tumour size (E. coli, p=0.019; PBS, p=0.0013) (figure 2B and C) in AOM/DSS-induced male CRC mice. Consistently, same results were observed in AOM/DSS-induced female CRC mice (figure 2D–F). During the period of gavage, there was no difference in body weight among different groups of mice (online supplemental figure 3 and online supplemental figure 4), indicating that L. gallinarum suppresses intestinal tumourigenesis in AOM/DSS-induced CRC in both male and female mice.

L. gallinarum modulates the gut microbiota of ApcMin/+ mice

To investigate the effects of L. gallinarum on gut microbiota, we performed 16S rDNA gene sequencing on ApcMin/+ mouse stool samples after gavage of L. gallinarum for 8 weeks. The microbial abundance in L. gallinarum group significantly increased compared with PBS (p<0.05), while there was no difference between L. gallinarum and E. coli groups (figure 3A). Similarly, although the β-diversity of stool samples from L. gallinarum-gavaged mice had a distinct trend compared with other two groups, there was no statistical significance (figure 3B). However, L. gallinarum could enhance abundances of some well-characterised commensal probiotics including Lactobacillus helveticus, Lactobacillus reuteri and OTUs from the Bacteroidetes phylum (figure 3C). Moreover, some genera, such as Alistipes, Allobacterum, Dorea, Odoribacter, Parabacteroides and Ruminococcus with species of pathogenic potentials, exhibited significantly decreased abundances in mice treated with L. gallinarum compared with control groups (figure 3C).
Gut microbiota

together, although _L. gallinarum_ could not change the overall gut microbiota composition, it could enrich abundances of probiotics and potentially deplete gut pathogens.

**_L. gallinarum_ supernatant inhibits the viability of colon cancer cells**

To validate the tumor-suppressive effect of _L. gallinarum_ in _vivo_, we performed _in vitro_ functional analyses using two CRC cell lines (HCT116 and LoVo) and a normal colonic epithelial cell line (NCM460) as control. Treatment with the culture supernatant of _L. gallinarum_ significantly reduced the viability of CRC cell lines in a concentration-dependent manner, but not in normal colonic epithelial cell line as determined by cell viability assay (figure 4A–C). Similar results were observed in colony formation assay in which HCT116 (ECCS, _p_ = 0.0002; BHI, _p_ = 0.0003) and LoVo (ECCS, _p_ = 0.0001; BHI, _p_ = 7.6 × 10^{-5}) showed significant decrease in colony compared with ECCS or BHI groups (figure 4D). These data indicated that the secreted molecules from _L. gallinarum_ could suppress viability and colony-forming ability of CRC cells.

**_L. gallinarum_ supernatant promotes apoptosis in CRC cells**

To determine the mechanism by which LGCS suppresses CRC cell viability, the effects of LGCS on apoptosis and cell cycle distribution were assessed quantitatively by flow cytometry with Annexin V-PE and 7-AAD staining. We found that LGCS significantly promoted apoptosis in CRC cell lines, HCT116 (ECCS, _p_ = 3.3 × 10^{-6}; BHI, _p_ = 5.1 × 10^{-6}) (figure 5A) and LoVo (ECCS, _p_ = 1.4 × 10^{-5}; BHI, _p_ = 3.6 × 10^{-7}) (figure 5B), while it had no effect on normal epithelial colonic cells, NCM460 (figure 5C). Moreover, we confirmed this apoptosis-inducing property of LGCS on CRC organoids derived from 2 patients, 74 (ECCS, _p_ = 1.2 × 10^{-5}; BHI, _p_ = 0.0013; BHI, _p_ = 0.0016) (figure 5D and E). By contrast, LGCS had no effect on cell cycle distribution in CRC cells (figure 5F–I).
Antitumour molecules produced from *L. gallinarum* are non-protein with a molecular weight <3 kDa

To investigate the features of anti-CRC molecules produced from *L. gallinarum*, bacterial culture supernatant was separated into low molecular weight (LMW) (<3 kDa) and high molecular weight (HMW) (>3 kDa) fractions using 3 kDa filter units. We found that decrease in viability of CRC cells was observed only in those treated with LGCS LMW fraction, while LGCS HMW fraction had no suppressive effect on CRC cells (figure 6A). Meanwhile, both heat-inactivated LGCS (figure 6B) and proteinase K-treated LGCS (figure 6C) retained the ability to reduce cell viability of CRC cells. Collectively, these results indicated that the anti-CRC properties of *L. gallinarum* could be induced by non-protein molecules with a molecular weight <3 kDa.

Figure 4  *L. gallinarum* supernatant inhibits the viability of colon cancer cells. The proliferation of cells was measured by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay. Different concentrations of culture supernatant were used for culturing CRC cell lines, HCT116 (5%, 10%, 20%) and LoVo (5%, 10%, 20%) and normal colonic epithelial cell line, NCM460 (5%, 10%, 20%). (A) The culture supernatant of *L. gallinarum*, especially in 10% and 20%, significantly suppressed the cell growth of HCT116 from day 4 to day 5. (B) The cell growth of LoVo was also significantly suppressed by the culture supernatant of *L. gallinarum* with different concentrations; both 5% and 10% from day 4 to day 5, and 20% from day 3 to day 5. (C) No change in cell growth could be observed in normal colonic epithelial cell line. (D) 20% LGCS suppressed colony formation of CRC cells. P values are calculated by two-way analysis of variance. ****P<0.001, *****p<0.0001. BHI, brain heart infusion; CRC, colorectal cancer; ECCS, *Escherichia coli* culture supernatant; LGCS, *Lactobacillus gallinarum* culture supernatant.
We next performed non-targeted LC-MS/MS to identify anti-CRC metabolite(s) in the LGCS-LMW fraction (online supplemental table 2). Score plots of principal component analysis (PCA) showed clear separations among LMW fractions of LGCS, ECCS and BHI groups (figure 6D). Differential abundance analysis showed the critical products generated from *L. gallinarum* that may contribute to the anti-CRC effects (figure 6E). To verify if *L. gallinarum*-produced LMW molecules are responsible for the anti-CRC effect in vivo, we then examined the intestine metabolomics by using faecal samples from *Apc*<sup>Min/+</sup> mice under different treatments (online supplemental table 3). Daily administration of *L. gallinarum* caused a significant overall compositional alteration of the gut metabolites as revealed by principal coordinate analysis (figure 6F). We found that metabolites including L-tryptophan, palmitic acid, 4-pyridoic acid and gamma-L-glutamyl-L-glutamic acid were significantly upregulated in mice after *L. gallinarum* gavage as compared with control groups (figure 6G). Among them, L-tryptophan was the most upregulated metabolite secreted by *L. gallinarum*. L-tryptophan is commonly converted into its downstream metabolites by gut microbiota.21 We anticipated that *L. gallinarum*-produced L-tryptophan and its downstream metabolites could be responsible for the anti-CRC effect exhibited by *L. gallinarum*.

**L. gallinarum** produces and catabolises L-tryptophan to release indole-3-lactic acid to protect against CRC

To further confirm L-tryptophan production by *L. gallinarum* and its conversion into downstream metabolites, we performed high-throughput targeted L-tryptophan metabolic profiling using culture supernatant at the late-stage stationary phase of *L. gallinarum* to ensure sufficient release and metabolic conversion of the metabolites (online supplemental table 4), as well as faecal samples from *Apc*<sup>Min/+</sup> mice (online supplemental table 5). The PCA plot regarding L-tryptophan and its downstream metabolites showed obvious separations among LGCS, ECCS and BHI (figure 7A). Stool samples from *L. gallinarum*-treated *Apc*<sup>Min/+</sup> mice also displayed clear separations from *E. coli*-treated or PBS mice (figure 7B). Differential abundance analysis showed that, in contrast to the log-phase culture supernatant, L-tryptophan was decreased in the stationary-phase LGCS (figure 7C), suggesting that *L. gallinarum* could catabolise L-tryptophan. In particular, we found ILA, which is one of the downstream catabolites from L-tryptophan, was highly enriched in both LGCS (figure 7C) and stool samples from *L. gallinarum*-treated *Apc*<sup>Min/+</sup> mice (figure 7D).

We then performed functional investigation of ILA in CRC cell growth in vitro and in CRC tumourigenesis in vivo. As shown in

---

*Figure 5*  
*L. gallinarum* supernatant promotes apoptosis instead of cell cycle arrest in CRC cells. (A) LGCS significantly promoted apoptosis including both early and late phases in two CRC cell lines HCT116, and (B) LoVo, but not in the normal colonic epithelial cell line (C) NCM460. (D) The size and number of CRC patient-derived organoids was visually reduced in medium containing 10% LGCS. (E) LGCS significantly promoted apoptosis including both early and late phases in CRC patient-derived organoids. (F) LGCS had no effect on cell cycle distribution in HCT116, (G) LoVo and (H) NCM460. P values are calculated by one-way analysis of variance. **P<0.01, ***P<0.0001. BHI, brain heart infusion; CRC, colorectal cancer; ECCS, Escherichia coli culture supernatant; LGCS, Lactobacillus gallinarum culture supernatant; PI, propidium iodide.
**Figure 6**  Antitumour molecules produced from *L. gallinarum* are non-protein with a molecular weight <3 kDa. (A) LMW-LGCS but not HMW-LGCS significantly suppressed cell growth of HCT116 and LoVo. (B) Decrease in proliferation of CRC cells was observed in heat-inactivated LGCS. (C) Decrease in proliferation of CRC cells was observed in PK-inactivated LGCS. (D) Score plots of PCA revealed clear separations of metabolites in culture supernatant of *L. gallinarum*, *E. coli* MG1655 and BHI groups. (E) Heatmap analysis revealed the abundance of different metabolites in LGCS, ECCS and BHI groups. (G) Heatmap analysis revealed the abundance of different metabolites in the gut of *Apc*<sup>Min</sup> mice under different treatments. P values are calculated by two-way analysis of variance or Student’s t-test as appropriate. *P<0.05, **p<0.01, ****p<0.0001. BHI, brain heart infusion; CRC, colorectal cancer; ECCS, *Lactobacillus gallinarum* culture supernatant; HMW, high molecular weight; LGCS, *Escherichia coli* LGG culture supernatant; LMW, low molecular weight; PBS, phosphate-buffered saline; PCA, principal component analysis; PK, proteinase K.

**Discussion**

In this study, we demonstrated for the first time that oral administration of *L. gallinarum* reduced intestinal tumour number and size in *Apc*<sup>Min</sup> mice and confirmed in AOM/DSS-induced CRC mouse model, indicating that *L. gallinarum* suppresses CRC tumourigenesis in both male and female mice. From *in vitro* experiments, we found that small non-protein metabolites produced by *L. gallinarum* suppressed the growth of CRC cells and CRC patient-derived organoids by promoting apoptosis.

Certain probiotics can suppress the progression of CRC in preclinical experiments. For example, both living and heat-killed *L. rhamnosus* GG (LGG) have anti-CRC effect by promoting apoptosis in human CRC cells. In an animal model, LGG could suppress CRC development by increasing expressions of various pro-apoptotic proteins such as Bax, casp3 and p53. Several studies have suggested that regular consumption of probiotics may improve the imbalanced intestinal microbiota, thus reducing the chance of chronic inflammation and production of carcinogenic compounds during intestinal dysbiosis.

In the present study, we found that *L. gallinarum* significantly enriched the abundance of well-characterised commensal probiotics, such as *L. helveticus* and *L. reuteri*. While some...
potential pathogenic species, such as Alistipes, Allobaculum, Dorea, Odoribacter, Faecalbacteroides and Ruminococcus,35–37 were significantly depleted in mice treated with L. gallinarum, L. reuteri is known to suppress inflammation-associated colon carcinogenesis by producing histamine.38 Thus, L. gallinarum suppresses CRC at least in part through enriching abundances of probiotics and depleting potential CRC pathogens. Gut microbiota plays a critical role in CRC tumourigenesis. Our previous study showed that transplantation of faeces from patients with CRC can promote tumourigenesis in germ-free mice and AOM-treated mice.39 Another study demonstrated that transplantation of faecal samples from AOM/DSS mice to germ-free mice led to increased tumour development compared with those harbouring faecal samples from naive healthy mice.40 These studies suggest that gut dysbiosis contributes to tumour susceptibility and alteration of the intestinal microbiota is an important determinant of colon tumourigenesis. Meanwhile, some studies found that probiotics can alter the composition of microbiota to alleviate cancer progression. For example, Lactobacillus salivarius Ren could suppress CRC tumourigenesis via modulating intestinal microbiota.41 42 These findings collectively inferred that probiotics like L. gallinarum suppress CRC development through modulating gut microbial composition.

We also demonstrated that metabolites produced by L. gallinarum could suppress CRC cell viability through inducing apoptosis. Using metabolomic analysis, we found that L. gallinarum could produce L-tryptophan and convert L-tryptophan to its catabolites.43 ILA was also found to have regulatory effect on intestinal innate immunity, which plays a specific role in host-microbe crosstalk. CRC is influenced by the balance between microbial production of health-promoting metabolites (eg, short-chain fatty acids) and
potentially carcinogenic metabolites (eg, secondary bile acids). Previous studies demonstrated the anticarcinogenic attributes of probiotic metabolites, especially for those produced by L. plantarum. However, whether ILA secreted from L. gallinarum is the main metabolite for CRC suppression requires further investigation.

In conclusion, to our understanding, this is the first study to demonstrate the anti-CRC effect of L. gallinarum. L. gallinarum protects against intestinal tumorigenesis. Such action is associated with modulation of the gut microbial composition and secretion of protective metabolites including ILA to promote apoptosis of cancer cells. These findings may facilitate the development of therapeutic strategy using probiotics for prevention of CRC.
